pain. Vomiting usually occurs promptly and is persistent. In cases of intestinal rupture it is present without exception. Tenderness is marked over the damaged organ. Spasm and rigidity appear with peritoneal involvement. The pulse is usually rapid and feeble; the temperature remains subnormal until infection occurs. The stomach is rarely injured by non-penetrating wounds of the abdomen but occasional rupture does occur. This is accompanied by all the signs of an abdominal catastrophy. Injuries to the intestine vary greatly. The gut may be crushed, ruptured or torn; it may be stripped from its mesentery. The ileum is more commonly injured than any other portion of the intestinal tract. The symptoms of severe intestinal injury are those noted above. Persistent vomiting is a most important sign. Pain remaining localized in one area for a long period of time is also very suspicious. It is to be remembered however that in injuries to the jejunum, symptoms are often delayed for 8 hours or more. In injuries to the liver, there is commonly a laceration or so called fracture of liver tissue. The symptoms are those of severe intraabdominal injury with hemorrhage, the later often being outstanding. The same is true in injuries to the spleen. In each of these there is tenderness and pain over the site of the damaged viscus. Injuries to the pancreas are severe in that pancreatic juice is liberated and sets up marked peritoneal irritation. Injuries to the bladder except rupture give few symptoms except bleeding Injuries to the bladder are frequently associated with fractures of the pelvis or result from blows or falls when the bladder is full. Ruptures of the bladder may be intraperitoneal or extraperitoneal. In either event there is pain and tenderness over the bladder region with difficulty of voiding and possibly blood in the urine. The intraperitoneal rupures cause symptoms of peritonitis while the extraperitoneal injuries cause pelvic cellulitis. Both varieties are serious and demand prompt recognition and early treatment. The test of injecting some sterile water into the bladder through a catheter and then aspirating is quite reliable. If we get all the water back, the chances are that the bladder is whole; if not we suspect rupture. It is to be kept in mind that rupture of the bladder is accompanied by considerable shock as a rule. We need spend no time discussing the penetrating type of abdominal wounds for these so obviously require immediate surgery, that no indecision remains in the mind of the physician.

# THE DOCTOR AS SEEN BY THE DETAIL MAN

By J. B. MARTELL, NEW YORK, N. Y.

An assemblage such as a medical convention permeates every one of us who does not belong to the medical profession with that great human feeling of helping our fellow man. It brings home to us a realization of how helpless we human mortals are, -- and how care-

The Doctor, looked upon as a hard shelled being by most, as a philanthropist by those who use his services and forget him later, and in general as the party to see when there is no further excuse for not doing so, is after all a human being who has had so many years of close contact with the many miseries of life, that he is either callous or ultra sensitive to the same things which affect the layman, only to the latter it often seems as if the physician's reactions are the reverse of his own.

The doctor is, and possibly rightly so, supercritical. Before committing his mind to any new and insufficiently proven theory, he requests facts, and to get the truth he observes the gradual evolution of clinical data from the embryonic state of theory through various forms of development until he has sufficient successful evidence to accept it as a fact. He deals with health, a thing more precious than life itself. He is the expert mechanic of the human machine, the most wonderful piece of machinery imaginable; a machine of beauty, of power, of speed, and greatest of all the only machine with imagination, with the problem of human behavior, a subject hard to solve and much harder to control.

Health is the living millennium sought by all, obtained by most people and maintained by a very few. Health is a condition in which we live longest and enjoy most,-but not many realize the full value of this statement; if they do, man has less control over his desires than he takes credit for.

When we consider the actual everyday carelessness of the enlightened person in the protection of health and compare it with the serious, methodical, painstaking patience of the medical profession in guarding and guiding us, we are compelled to realize how often we have a distorted picture of the relation of loctor and patient.

A person usually does not become a patient until he has used and abused his body, till even the history of his case has been lost in a mind full of evasions and alibis, of attempts to put off having to visit a doctor. Then he usually comes to the doctor in a frame of mind like that of a person served with a summons for neglecting time and again to pay the money borrowed from a friend. One is mentally and

financially broke, and the other mentally and physically.

I believe that in the doctor's ever persistent campaign for health he is not as strict with the public as he would sometimes like to be, being too careful to not injure the feelings. of his patients. He has achieved miracles when we consider the lack of co-operation and credit he receives from and by the public.

The manufacturers of things that belong to "doctors only" have been and now are a constant worry to the profession in its fight for better general health. This phase of the practice of medicine has been and is of the greatest interest to the officers of medical supply houses, and therefore we are constantly seeking to learn more about the best and proper methods to pursue in serving the doctor in a dignified and ethical way. To receive real cooperation from the doctor we feel we must let him know our answer to the various questions that decide the ethics of practice as we see them.

After days of associating with what to me is the most scientific body of men, I will attempt to answer the questions often put to me.

- Q. "Do you think your product will do as well with the medical profession as it would by going direct to the laity?"
- A. "Yes! Decidedly yes, and better. To wipe out any chance of this being an evasive answer allow me to say I mean from a humanitarian standpoint as well as a financial point of view."
- Q. "Don't you think doctors will take their own sweet time in prescribing your product?"
- A. "Yes, and they should. Rome was not built in a day-but was destroyed in that time. We are having wonderful results at this time."
- Q. "What will you do to sell your product to the medical profession?"
- A. "Let them use it in clinics or such private cases as have resisted other things now prescribed. This has been our only program."
- Q. "Don't you think that doctors are satis-
- fied with the medicines they now have?"
  A. "No! Decidedly not. The apex of perfection has not been reached and no doctor by act or statement will claim it has."
- Q. "What is your opinion of how you can assist the doctor in selling your product?"
- A. "No man, group of men, or corporation manufacturing a product to sell should ever be so unscrupulous or careless as to let the acquisition of dollars and cents blind them to the fact that human life, health, and happiness are at stake. I personally feel that any manu-

facturer of an ethical product should have and retain the same dignity and standards as the profession he serves. He cannot help the doctor; 'the doctor can help him;' but he can help the public by giving them honest advice on general health. In this way you will help the doctors realize their ambition of making health as contagious as disease."

Q. "Why do some people have no confi-

dence in doctors?"

A. "Nonexcusable ignorance is the answer. An ignoramus will take his motor car to a garage and have an irresponsible mechanic look at it, tighten the steering wheel and do such other things as may or may not be necessary and then take his car out on the highway and drive 70 miles an hour, placing his life in the hands of a mechanic. This same man or woman will put off seeing a doctor until some morning when the old human machine refuses to go any place else, and then if the doctor does not perform a miracle, well, he just doesn't receive his full credit."

People are either stingy, careless, or ignorant, who don't treat themselves at least as they would a metal machine. To see a doctor at least twice a year is the most economical program for Mr. Public; and remember, doctors do not get rich on minor cases, and so they have no money-making intentions in

preaching this gospel of health.

The following is the type of information we like to put before the public, and which we will be glad to place at the disposal of the medical

profession in the form of blotters or other suitable pieces.

Health is a condition in which we live longest and enjoy most.

An automobile is not nearly the most abused machine in the world, when compared to the human body.

A machine will function only commensurate with the care it receives by its operator.

Your body is a wonderful machine with many intricate parts that must co-ordinate for good health.

When you hear a knock in the engine of your car, you run for a mechanic,—but most people must be knocked down and carried to a doctor.

Remember there are no spare parts to the human body. At least take care of what you have.

If you had to buy your physical self as you do a car, you would respect it more.

See your doctor at least twice a year, and multiply your pleasure at least ten times.

Health is the condition in which we live longest and enjoy most.

### TREATMENT OF CONSTIPATION

By EDWIN BOROS, M.D., NEW YORK, N. Y.

THE difficulties encountered in the formulation and choice of a method in the treatment of constipation, has been as unsatisfactory as disappointing, which attests the uncertainties of the various agents we have on hand with which to combat this universal and troublesome complaint. The variety of medicaments in vogue, with their irritating tendencies, the many diets and physical agents which are relied on to assist in rendering relief, confirm the lack of a uniform and reliable method which gives the most satisfactory results in the majority of cases.

The manifold ideas of the causation of constipation still remain theories, and their discussion will not be considered except for one thought, which might be emphasized because of its significant bearing on the treatment. Constipation is a by-product of civilization. It is rare in animals except in those which have

been domesticated, such as the dog for example, and it is of interest to note, how commonly it preponderates in those individuals such as letter-carriers, policemen, etc., who by reason of their calling, are unable to respond to the defecation reflex, with a resultant impairment of the reflex. This suppression of defecation as well as that of the passage of intestinal gases is an important causative factor in the production of constipation. If we consider the cause of constipation as primarily due to the loss of this defecation reflex, then its reestablishment is a matter to which we must bend our efforts if we are to look for a permanent restoration of bowel function.

In our search for newer remedial ideas and measures, we might overlook some of the time honored substances which are relegated to the background, many of which have been discarded because of limited success in their use. It

might be considered trite to emphasize, that any substance, no matter how good, if not properly applied is of no value, and naturally can only be discredited. I have been enthused and encouraged by a well defined routine, which if directed to those cases of constipation, unassociated with definite pathological findings, have given remarkable results in the establishment of regular bowel movements. No originality for this method is claimed, and it is my purpose to bring before one's notice, a feasible and easy method for the treatment of constipation, having for its basis long established facts, the utilization of which will render a definite working basis, with gratifying results. There is no gainsaying that laxatives are most pleasant and easiest to take, but their irritating tendencies and subsequent unreliability after prolonged use, contraindicates them. Of the many methods for combating constipation, the recourse to enemas is most to be decried. Not only do enemas dilate the sigmoid and rectum, producing a consequent atony if one does not already exist, but the tendency is to over irritate, so that the defecation reflex becomes worse, and these cases never become cured. Enemas might well be used in acute conditions of bowel stasis, or in small amounts in the treatment of colitis, in quantities of 200 to 300 cc., but should not be used for chronic constipation.

The method I am employing with great satisfaction is based on the use of concentrated sugars, which in this state are not quickly absorbed. They are incompletely split in the small intestine, and reach the colon where they ferment. The routine I am using is as follows: The patient receives two tablespoonfuls of lactose in one-half glass of cold water one half hour before breakfast. The use of cold water is preferable because it has a tedency to stimulate the gastro-colic reflex. This is followed at 10 A.M. by the ingestion of a moderate amount of figs, prunes, dates or grapes. Six to ten prunes, figs or dates is the usual average necessary, or by preference one-half pound of

grapes if desired, may be taken. The effect of prunes is enhanced by soaking them previous to ingestion in water for two hours, so as to encourage early fermentation by the fermentative organisms present. In this way, by the time the sugar has reached the small intestine, the process of fermentation has already begun. At 4 P.M., the 10 A.M. program is repeated, and prior to retiring, two tablespoonfuls of lactose is again administered. The addition of fats in large amounts is especially recommended in the undernourished constipated individual, whereby we gain the added physiological irritation of the small intestine produced by the soaps which are formed. There is considerable gas formation with the use of lactose, and its propelling action should not be curtailed by suppressing it, but on the contrary, the patient should be encouraged to aid in its escape through the rectum. An occasional diarrhœa resulting from the lactose administration, can readily be controlled by the reduction of the dosage.

As a rule, a few days are required before noticeable results are manifest. In the meantime magnesium oxide powder is prescribed, one teaspoonful of which is to be taken thrice daily on the first day, one-half teaspoonful thrice daily on the next day, and in one-quarter teaspoonful doses on the third day, its administration to cease after the third day. In obstinate cases during this three-day interval, where no bowel movement occurs, the patient is to inject a bland oil into the rectum before retiring, to be next morning followed by an enema containing a small amount of water if necessary.

The feature of the above regimen, aside from the results obtained in the majority of cases of uncomplicated constipation, is the avoidance of artificial irritants. Of importance is the emphasis to be laid on training the rectum and regulating defecation, so that daily use of the toilet is made regularly during the same time each day.

#### THE HYPERTENSIVE HEART\*

By JAMES P. O'HARE, M.D., AND WILLIAM EGLOFF, M.D., BOSTON, MASS.

From the Medical Clinic of the Peter Bent Brigham Hospital, Boston, Massachusetts. Work assisted by the Fund for Vascular and Renal Diseases,

**7**OUR secretary has asked us to talk to you about the problem of the heart in We have assumed that hypertension. what you want is a summary of our presentday knowledge of this very important problem. You can readily realize its importance when we remind you that "Circulatory Disease," of which this forms by far the greatest and most vital part, has increased tremendously of late. Figures from the entire Registration Area in the United States show an increased death rate from this group of diseases of 69 per cent from 1904-1922. Fifty per cent of the declinations of almost any Life Insurance Company have been for "Circulatory Disease" and this percentage has been steadily increasing in the last decade. Finally, a large portion of the patients from forty to sixty years of age that come to you with heart trouble have or have had at some time high blood pressure. To be sure, there are a few whose heart disease follows hyperthyroidism. rheumatic infection, and syphilis, but for the most part your "cardiac" beyond middle life is the result of a small blood vessel arteriosclerosis associated usually with hypertension.

You will, of course, realize that in the brief time at our disposal, it is quite impossible to do justice to such a vast subject. One can

only touch the high spots.

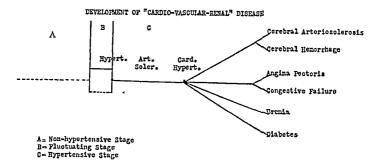

1924. (Boston Medical and Surgical Journal, Vol. CXC, 1924, page 683.)

When a patient comes to you with hypertension, you may be concerned not at all with the cardiac condition, or it may require most of your attention. In order properly to understand the part played by the heart in any such case, it is necessary to know the development of the hypertensive arterial process and the relationship that one part bears to another.

In the accompanying chart we have sketched for you our conception of the development of the hypertensive process and the relationship between the various disorders in the vascular tree.

According to the prevalent theory, hypertension is largely a hereditary disease and shows itself in early life in a pre-hypertensive stage. Certainly between the ages of ten and twenty, many of our patients gave evidence in a weakened vasomotor system that they were due to have circulatory disease about middle life or later. More than half gave a history of such vasomotor symptoms as abnormal flushing, blushing and sweating, frequent nose bleeds, abnormal menstruation, cold, blue sweaty hands and a highly nervous temperament.

These vasomotor individuals from vascular

The data on which this paper is based come from a study of a hundred "living" cases of hypertensive disease and a hundred cases that have died and come to autopsy. A study of the first group was published previously in

Read at the Annual Meeting of the Fifth District Branch Medical Society of the State of New York at Watertown, New York, October 17, 1929. families in the third and fourth decades in life seem to be the vigorous, ambitious workers who readily assume great responsibilities. Their strenuous mode of living is the second factor in the production of hypertension. Many of them, too, towards the latter part of this period develop the habit of overeating and, as a result, usually put on considerable weight.

This may be a third factor in the production of this circulatory disease.

At about thirty-five or forty years of age such an individual usually begins to show occasional rises in the blood pressure above the line of normal. If one could follow closely such a case he would see that the blood pressure on a day when the patient was nervous or tense registered ten or fifteen millimeters above normal and on the next day it might be normal again. As a result of various temporary stresses the pressure rises, to fall again to normal, with release from the strain. Very gradually, the upward excursion becomes greater and the fall less until eventually-perhaps after five to ten years—the pressure becomes permanently above normal. From this point on the pressure rarely falls to normal unless from great cardiac weakness, coronary infarction, acute hemorrhage or complete Shortly after this permavasomotor collapse. nently hypertensive stage appears, one finds evidence of small blood vessel arteriosclerosis in the eye-grounds. The condition of the retinal vessels is the only index we have during life of the condition of similar vessels throughout the body. It is these vessels that are all important and not the vessels of the calibre of The condition of the radials and brachials. these vessels in the fundi, too, indicates fairly satisfactorily the condition of the cerebral vessels of similar character in back of them. Thus they may warn you of the possibility of a cerebral hemorrhage.

Shortly after the permanently hypertensive stage develops, one can find cardiac hypertrophy. From that point on, the case may develop more or less rapidly along any of the lines illustrated in the chart. The process may advance along the cerebral route and our patient may have a cerebral accident or a more generalized cerebral arteriosclerotic disorder. The arterial disease may advance more rapidly in the heart and great vessels and the patient die from congestive failure or angina pectoris. The course may be almost entirely within the kidneys and our patient die of uremia. Finally the vascular disorder may be responsible for Without doubt the process advances into other organs harder to reach and, therefore, harder to estimate.

It is extremely important to realize that the disturbance is rarely confined to any one of these channels. If this is borne in mind, we will have no difficulty whatsoever in explaining the curious combinations that occasionally occur. A patient may have as his chief and only symptom angina pectoris, and yet may die of a cerebral hemorrhage. Again, you should never forget that your diabetic patient may die from angina pectoris or congestive failure. Again your old chronic nephritic may

have a very important congestive failure added to his picture before death. From this chart, you can well see that in any given hypertensive case, your heart may be of very little importance or it may be the weakest link in the entire chain, and you must never regard a case of hypertension as strictly a cardiac one merely because the heart symptoms predominate or a renal one because he has albumen and casts in the urine. You must think broadly about the condition and remember that you are dealing with small blood vessel sclerosis of the entire vascular tree.

We cannot, of course, go into the symptomatology, signs, etc., of all the various disorders of this large vascular tree. We must confine our discussion to the heart.

Of what cardiac symptoms does the hypertensive patient complain? The most frequent symptom is, of course, dyspnea, and this occurs in approximately two out of three cases. The dyspnea may be of various types. It varies from slight breathlessness on considerable exertion to marked respiratory difficulty even when quiet. Cheyne-Stokes breathing is a frequent occurrence as a terminal event. Cardiac asthma occurs in about ten per cent of these cases. A most important type of dyspnea that deserves special mention is the closely related paroxysmal nocturnal smothering. As a rule, this is found comparatively late in the disease and it is closely associated with angina pectoria in its origin and its response to nitrite therapy. The symptom has no fixed relationship to the height of the blood pressure, but is more commonly found in those with high diastolic pressures.

Acute pulmonary edema was not very common in our cases, even in those that went on to death.

Cardiac pain is most commonly present as a dull ache in the region of the apex and lower precordia. Pain at the base of the heart, not the classical angina, is less common. Typical angina occurred in only three of our hundred living cases, and in approximately twice that number in those that died. On the other hand, Levine has found that sixty-five per cent of his cases of angina pectoris have hypertension and that forty per cent of his coronary infarction cases were known to have had hypertension. Not infrequently, the patient complains of tenderness in the region of the apex of the heart.

Of the cardiac signs, hypertrophy is, of course, the commonest abnormality found, and is usually found by the ordinary methods of physical examination. Although palpation and percussion usually disclose the enlargement of the left side of the heart, one is not impressed with the "bigness" of the heart in hypertension until he has studied the weights of such

hearts at necropsy. The average weight of the normal adult male heart is approximately 300 grams and of the female heart 250 grams. In our series of one hundred hypertensive cases, the male hearts average 581 grams and the female hearts 479 grams.

Occasionally physical examination does not show enlargement of the heart. A 7-foot x-ray plate of the heart should, however, in practically every case, show such enlargement. You know that in such a film, the total width of the heart should not be more than one-half the width of the interior diameter of the chest. Rarely do you have to depend upon an electrocardiogram to show left ventricular preponderance. In fifty electrocardiograms taken on living hypertensive patients, 30 out of 50 showed left ventricular preponderance; 29. however, showed no preponderance at all; 1 showed questionable right preponderance. In the one hundred cases that came to post mortem, electrocardiograms were made on 55. Of these, 35 only showed left ventricular preponderance: 2 showed right ventricular preponderance. This lack of left ventricular preponderance in hearts that are obviously enlarged to the left is often disconcerting until we realize that the electrocardiogram indicates merely deviation from an axis that may not be quite the usual one. The lack of preponderance is explained at times by the fact that both sides of the heart are equally hyperthropied.

The condition of the great vessels in hypertension is one of considerable interest. In practically every case of any duration, changes take place. There is a diffuse widening of the aortic arch often associated with well marked tortuosity. This widening may occasionally be found by ordinary physical examination, but one should not place too much confidence in the supra-cardiac dullness determined by percussion. On the other hand, 7-foot plates of the heart are trustworthy and in a series of fifty such plates, the aortic arch was widened in fifty per cent. This widened shadow may be due to dilatation, or to tortuosity, or to both. As is so often the case fluoroscopy is frequently better than a flat film for disclosing the tortuosity and in addition a somewhat characteristic sharp pulsation at the upper end' of the ascending portion of the arch. Chandlee and Holmes\* feel that under fluoroscopy the heart shows a characteristic marked pulsation of the whole cardiac field, particularly the aorta. Closely associated with this diffuse dilatation of the aorta are certain murmurs of the heart. These may be of three types. The commonest is a simple blowing systolic murmur at the base, extending up into the neck.

The second is a similar coarse systolic, often associated with an arteriosclerotic aortitis. The third is a less common and often transient diastolic whiff heard in the aortic area and along the upper left border of the sternum. Its exact origin and significance is still unknown. Post mortems on such cases do not show any aortic insufficiency. Systolic murmurs at the apex are quite common and occur in more than two out of three cases. These are undoubtedly due to relative mitral insufficiency and are probably of very little importance.

Closely related to the dilated aorta, and worthy of mention is the pulsation in the vessels of the neck. While pulsations may be noted in the suprasternal notch and in both supra-clavicular regions, the most marked pulsation is in the right supra-clavicular region, occasionally associated with a tortuous carotid artery and rarely associated with an elevation of the right subclavian artery.

The second sound in the aortic area is accentuated in more than one-half of the cases and it is frequently ringing. Allbutt's tympanic note, said to be characteristic of aortitis, has been rarely found in our experience. The character of the apical first sound is of very great importance, indicating, when properly interpreted, the condition of the myocardium. In our series of "living" cases, about one in three showed weak first heart sounds and one in four an accentuated sound. As could be expected in the series that died, almost one in two showed a weak mitral first sound and only one in ten an accentuated first sound.

The rhythm of the heart in hypertension is usually regular, although some irregularity may be found at one stage or another in about a third of the cases. The commonest type of arrhythmia is that of extra-systole. Somewhat more than a quarter of our cases showed extra-systoles at one time or another. These extra-systoles usually originate in the ventricle but many are found to be auricular in origin. Paroxysmal tachycardia was found in only two out of two hundred cases. Auricular fibrillation occurred in eleven per cent of our "living" cases and in seventeen per cent of those that Defective intra-ventricular conduction died. occurred twice in our "living" cases and four times in those that died. Partial heart block occurred once in the former group and once in the latter, but complete heart block was noted in five cases of those that died. Nodal rhythmoccurred once in the latter group. Electro-cardiograms not only showed left ventricular preponderance in most of the cases of hypertension, but also showed changes in the character of the T-wave. This change is in the

nature of a negative or diphasic character in

American Journal of Medical Sciences, 1921, Vol. CLXXVIII, page 364.

Lead I and sometimes in II. Willius\* reported that forty-two per cent of his cases with T-wave negativity in Leads I and II were associated with hypertensive cardiac disease.

# Prognosis

In trying to make a prognosis on a patient with hypertension, one must bear in mind all of the relationships we have indicated in the Patients may live fifteen to chart above. twenty years with high blood pressure. the other hand, in a patient with the so-called malignant hypertension, the whole course of the disease may be less than two years. The best way to judge the course of any disease is to watch it at intervals and note the rate and the course that it is travelling. Time is the great prognosticator. How important is the condition of the heart in the ultimate prognosis is indicated by the fact that in the group of one hundred cases of hypertension that came to necropsy, fifty-one died a cardiac death. Of these forty-three had congestive failure, seven coronary infarction, and one heart block. Only sixteen cases died a cerebral death, and eighteen a renal one. Fourteen patients died from miscellaneous causes, such as cancer (4), broncho-pneumonia (4) and one each of lobar pneumonia, peritonitis, lung abscess, hemorrhage, a dissecting aneurysm, and acute pyelonephritis.

We realize that the large predominance of cardiac deaths is not entirely in keeping with figures given by some other authors. We appreciate, too, that our group is comparatively small. Dwight, in "Life Insurance Medicine" states that in a very large group of insured cases, death occurred from heart disease, cerebral hemorrhage and chronic nephritis in about

equal proportions.

Confining our remarks to the heart itself, we may well say that the heart may perform good and efficient service throughout the entire course of vascular disease. Remember that a hypertrophied heart is not necessarily a pathological one. Remember, too, that a patient with considerable evidence of cardiac pathology may live for many years with absolutely no symptoms referable to his heart. If such a patient does not put his heart to any great test of effort and is content to putter about, he may deny that he has any cardiac symptoms whatsoever.

The prognosis of the heart in hypertension depends on three elements: First the amount of strain. This may be the general strain of living or the particular strain against which the heart is beating. The latter is indicated by the degree of arteriosclerosis and the height of the

diastolic pressure. Given a constant high diastolic pressure, the prognosis is poor. Usually, however, these patients with a diastolic pressure constantly above 130 die of a cerebral hemorrhage before the heart wears out. second element in prognosis is the condition of the coronary arteries. Obviously, disease of these vessels results in a poorer nutrition of the myocardium and a consequent decreased efficiency of the heart. Furthermore, the likelihood of death from angina and coronary infarction must always be borne in mind. Janeway's cases and in ours, seven per cent died of coronary occlusion. It may be well to indicate at this point what Levine has well said, that those cases of angina with systolic pressures under 160 or 170 are more to be feared than those whose pressures are considerably higher. The third factor in the determination of the prognosis is the condition of the myocardium, which may be the result of factors I and II. Here the evidence pointing to a grave outlook, consists of a poor response to effort, a weak first heart sound, a persistently high cardiac rate, gallop rhythm, pulsus alternans, defective conduction time, heart block, a low vital capacity and, perhaps, fibrillation. The negative T-wave in Leads I (and II) does not have as bad a prognostic value as it does in other forms of heart disease.

### Treatment

The question of therapy can quickly be dis posed of. The treatment of the heart in hypertension is the treatment of the general vascular disorder. This means a very definite cutting down of physical effort, and so far as possible a relief from nervous tension and stimuli, which tend to cause the blood pressure to shoot up sharply from time to time. Abundant rest at night and rest particularly after meals is absolutely essential. Enough daily exercise to keep the cardiac and skeletal muscles in optimum tone is also indicated. Walking is the best form of exercise and should be undertaken between meals. Where such exercise cannot be carried out, massage is of considerable value.

When attention must be given to the heart, the treatment of this organ is exactly the same as the treatment of heart disease in general. Congestive failure should be treated in the classical way with rest in bed, a restricted diet, morphia, perhaps, and digitalis. Right here, we should like to dispose of the false notion that digitalis is in any way contraindicated in high blood pressure. The indications for the use of this drug are exactly the same in high blood pressure as in low. If a rapid heart exists or if rapid fibrillation is present, digitalis should certainly be used. A blood pressure may rise after its use, but this is due to the

<sup>\*</sup> American Journal of Medical Sciences, 1926, Vol. DCXXX, page 175.

improvement in the condition of the heart muscle and we do not believe that the rise following the use of digitalis can ever be shown to have caused a cerebral accident. These usually come from a sudden physical or mental strain.

For angina pectoris or the nocturnal smothering, digitalis, euphyllin, theominal and diuretin are to be used for a prolonged effect. The last three of these drugs tend to produce a better circulation through the coronary vessels. For the immediate effect, nitroglycerine or amyl nitrite is indicated. These two drugs, as well as the other nitrites, have no place in the treatment of the hypertensive patient, except in angina pectoris or possibly in the cramps that sometimes occur in the legs. Bleeding may be of great value in congestive failure to relieve the right side of the heart. seems to have a very definite beneficial effect on the whole vascular tree and should be used more commonly than it is. The nerve sedatives such as bromides, chloral, codein, morphine and atropine are often extremely helpful.

Pulmonary edema, which at times occurs in these cases, may be treated by morphine and

atropine and by strophanthin, if the patient has not previously received digitalis. has, digitalis by injection may be tried. Bleeding is also of great value. Adrenalin has been fairly commonly used in the treatment of this condition, but we advise strongly against its use because of the sharp rise in blood pressure that follows its administration. Extrasystoles rarely require any treatment. When they are numerous and bothersome, bromides usually help. Quinidine may also be useful in such cases provided the heart muscle is good. In heart block barium chloride may be effective and possibly adrenaline and thyroid extract. In the paroxysmal tachycardias that do not respond to vagal or eye pressure, quinidine may be effective.

Finally we wish to conclude with the statement that cannot be reiterated too often. In hypertension the heart is only one element in the general vascular disorder. It may be a factor of the greatest importance or it may not concern us at all. The most intelligent treatment demands a thorough understanding of this point, as well as a thorough knowledge of the therapeutic elements offered above.

### HEADACHE WITH SORE SCALP

### By G. B. FERNLUND, M.D., RICHMOND HILL, N. Y.

HEADACHES due to nasal ganglion neurosis are very common but the general practitioner who first sees these cases and prescribes for them seldom makes a correct diagnosis. As little temporary and no permanent relief is given these patients by the theraputic measures commonly used, they frequently change doctors and often resort to advertised "Cure Alls."

Sufferers from this condition are almost always considerably over or under weight. In my experience unless they are under thirty years of age, they are usually overweight and in addition appear to be very healthy.

The most common location of this type of headache is first parietal, second occipital and third a combination of these two. Tenderness of the scalp over all or part of the affected area is very often present. Tenderness and stiffness of the posterior cervical muscles are common.

The headache may be extremely severe or so mild, the only complaint will be that the scalp is sore. It may vary markedly during the course of the day, but seldom entirely disappears. It

is usually worse in one specific spot, and this area of greatest intensity is very constant. The pain is usually described as being a steady ache, and often has a starting point on some part of the head other than the point of the greatest intensity.

Examination of the nose usually shows no signs of an acute infection but hypertrophic changes are always prominent. Examination of the posterior cervical muscles will often show them to be hard and when stiffness or tenderness is complained of nodular formation along the line of their occipital origin is common. These nodules are extremely tender and vary greatly as to size.

Proper treatment gives these patients immediate relief, and in a majority of cases complete freedom from headache. Permanent results are as a rule obtained by treatment, but if the case is resistant, injection of the sphenopalatine ganglion may be resorted to.

The type of headache herein described is but one of the many neurological syndromes that result from nasal ganglion irritation. These are so varied and important that the busy practitioner can well afford the time required to obtain a general idea as to their nature and manner of appearance.

Here is a brief outline of three typical cases:

Mrs. A. R. aged 27, wt. 126 (overweight 10 lbs.) well developed. Has been suffering for the past seven years from sore scalp over the right parietal region. During an attack she is unable to comb her hair or sleep on the affected side. During the past two years these attacks have been accompanied by headache both in the right parietal region, and occipital area. She has suffered frequently from colds and attacks of sore throat for which a tonsillectomy and submucous resection were done with much benefit. Nasal examination showed a dry, red mucosa with extensive hypertrophic changes. No active infection was found. Local application to the nasal ganglion gave immediate relief, and two or three treatments give periods of relief which have averaged six months in duration.

Mrs. M. C. aged 54, wt. 107 (overweight 20 lbs.) heavy set and robust looking. Eight years ago she had her first attack of severe headache located in the right parietal and occipital areas. Several minor attacks are recorded prior to onset of present illness. This last attack began nine months ago with severe headache over the right parietal and occipital regions, soreness of the scalp over the affected occipital area, so severe that she could bear no pressure, and soreness with stiffness of the posterior cervical muscles. She was confined to bed for a period of ten weeks and kept under the influence of opiates because

of the severe pain. She has changed doctors three times during this attack. Nasal examination shows chronic hyperplastic rhinitis with thickening of the mucosa in both antrums and anterior ethmoids. Examination of the muscles of the neck and shoulder showed them to be of hard with nodular formation along the occipital insertion of the trapezius muscles. Local application to the nasal ganglion gave immediate relief from the headache, relaxed the cervical muscles and caused the disappearance of the cervical nodules. Injection was required however to secure lasting relief.

Mrs. B. T. aged 32, wt. 160 (overweight 20 lbs.). First attack of headache similar to present complaint was eight years ago. She has had an average of six attacks a year since, mostly mild, some very severe. Present trouble started two weeks ago with a severe pain beginning in the occipital region and settling in the parietal area and also behind the eye of the same She is seldom troubled with colds and never has a sore throat. She had a severe attack of influenza ten years ago. Nasal examination shows hypertrophic changes limited to posterior halves of middle and inferior turbinates, on the affected side. Examination of the cervica<sup>1</sup> muscles shows marked tenderness along the line of their occipital attachment. She has changed doctors three times since the onset of this last attack. Local application to the nasal ganglion and the ethmoid nerves gave instant relief and after six treatments, there have been no recurrences in ten months.

# NEW YORK STATE JOURNAL OF MEDICINE

Published semi-monthly by the Medical Society of the State of New York under the auspices of the Committee on Publication. DANIEL S. DOUGHERTY, M.D......New York

### FALL ACTIVITIES

This issue of the Journal is the last one prepared during the summer vacation time. The fact that an abundance of up-to-date material has always been available is proof of marked progress in the Medical Society of the State of New York; for the Journal has always been able to record deeds well accomplished as well as aspirations,

The fall season opens auspiciously. This issue announces seven meetings of major importance during September. The secretaries of County Societies meet on the ninth; the chairmen of the committees and the Executive Committee on the eleventh; and the Committee on Public Relations on the eighteenth. Then come four District Branch meetings.

# PRESIDENT'S COMMENTS ON CURRENT EVENTS-NO. 5

Conference of Committee Chairmen: The President has asked the Chairmen of the Standing and Special Committees to meet him at ten o'clock on the morning of September eleventh at the office of the State Society in New York. He wants to get from each committee a concise written statement of the proposed program for the year, and to have each chairman report in the presence of other chairmen, so that each will know what the other is doing. The purpose of this meeting is to give the President a better grasp of the work of organized medicine, to unify the program, prevent overlapping with its resulting waste of effort and money, harmonize the relationships of the parts of the program to the whole program so as to do the most that can be done this year for the practice of medicine and for public welfare.

In the afternoon of the same day the President will present to the Executive Committee of the Council the proposed program for the year as outlined by the committees, for discussion and approval.

Doctor (?) Paul O. Sampson in New York Warning Against a Lecturer. In the Journal of the A.M.A. for July 12th, the Bureau of Investigation gave a report on Paul O. Sampson, who represents himself to be a food specialist and calls himself a doctor. Sampson is working among the service clubs of New York now. He addressed three in Albany the week of July 20th, as a representative of the Fruit & Vegetable Growers' Association. He spoke very freely, and to the layman very convincingly, of the amount of heart disease that is due to the lack of minerals afforded by vegetable diet. He cited instances where he had achieved miraculous results by advising chronic sufferers to change their diet. He frequently mentioned physicians with whom he worked and particularly the Superintendent of the Middletown Sanitarium. His climax was reached when he told his audience that anyone could avoid having cancer if he carefully selected the proper vegetable diet.

Physicians who are members of service clubs, will do well to advise their program committees of this man's record, as described in the Jour-

nal of the A.M.A.

Compensation Remuneration in Hospitals: Although the intent of the Workmen's Compensation Law is that the expense of treatment of compensation cases should be borne by the insurance carriers, it is alleged by certain hospitals that through practice and custom the hospitals are able to charge rates which only approximate sixty per cent of the cost to the hospital of such cases.

The City Club of New York recently made a study of the situation, and in the report it stated that the hospitals generally are not adequately remunerated for their services in compensation cases, and that innumerable incidental problems arise in the various hospitals with respect to the collection of fees, and the necessity of various kinds of treatment to patients in compensation cases. It was recommended:

 That a standard schedule of rates be drawn up for all hospital work, except that for which a fee is charged by the physician, such schedule to be mutually satisfactory to the hospitals and to the Compensation Bureau of the State Department of Labor, and discussed with the insurance carriers. It was suggested that these rates should apply to per diem care, to additional services such as x-ray and pathological treatments, etc., and to clinic care.

2. That there be established a Compensation Advisory Service for Hospitals as a cooperative enterprise on the part of the hospitals, such bureau to render certain services to hospitals. It was suggested that such bureau might be established on a three-year experimental plan through the interest of some fund or public-spirited philanthropist.

At a later meeting a Compensation Advisory Service Committee was named. Mr. Vincent Astor of New York Hospital was appointed Chairman, and to serve with him were named representatives from eleven hospitals, the State Department of Social Welfare, the Labor Bureau, Welfare Council of New York, and the American Association of Labor Legislation.

The State Society Public Relations Committee has been interested in this question during the last year, and has made several recommendations toward improving conditions. It will cooperate with the above named Advisory Committee for the purpose of including the entire state in the benefits that may arise from the Committee's work; and it stands ready to give constructive advice at any time. WILLIAM H. Ross.

### MEASURING COUNTY SOCIETY EFFICIENCY

Meetings of District Branches afford opportunities to apply standards of measurements to county societies:

To score their activities:

To compare one society with another;

To stimulate progress.

Physicians have a dual attitude toward county societies:

1. Receiving:

2. Giving.

· Receiving Benefits: The older attitude was concerned principally with the benefits which the physician received from the county society, especially its scientific papers and its sociability. That was a good meeting in which a doctor heard a practical paper read and swapped stories with his colleagues. Judged by the standards of scientific papers and sociability every county society deserves a high score.

Giving Service: The newer attitude of the relation of the physician to the county society is that of giving service.

Medicine is practiced by physicians as

1. Individuals;

2. Organizations.

The practice of medicine by the individual physician has two characteristics:

1. It is given to individual patients;

2. It is *curative*, and (a) deals with crippling conditions, and (b) covers only about one-third of the broad field of medical service.

The practice of medicine by organizations also has two characteristics:

 It is given to the people collectively and impersonally;

It is preventive, and consists largely of education, and the development of public sentiment in favor of preventive measures.

The people expect the medical profession to protect the community from sickness Individual physicians who compose the medical profession wish to give that protection, and are jealous of official boards of health and volunteer organizations that attempt to practice preventive medicine. Physicians have therefore slowly evolved the practical idea that the vague academic conception called the medical profession is the medical society of the county, the state, and the nation.

Examples of Standards of Measurement: The practice of medicine by county societies has been developed along definite lines, any one of which may be used as a standard of measurement. Practical standards are the records of each society in the following activities that are promoted by the State Society:

- 1. Reporting society meetings in the Journal;
- 2. Courses in graduate education given;

Public relations surveys made;

4. County laboratories;

5. County tuberculosis hospitals;

6. County public health nurses.

The eight district branches are the natural units within which these standards of comparison may be applied to the county societies.

W. H. Ross.

### LOOKING BACKWARD

### This Journal Twenty-five Years Ago

City Doctors in the Country: Competition of city doctors with their country brethren during summer vacations was a problem twenty-five years ago as acute as at present, as is shown by the following extract from the New York Times quoted in this JOURNAL of August, 1905:

"The country doctor naturally assumed that he was to share in the prosperity of his neighbors and patients, the agriculturists, who 'put' their products to the summer sojourner at prices from twice to ten times the local market. Visions of fees of \$1.50, per visit, instead of his customary 75 cents, began to flit alluringly before his eyes. But he forgot to allow for the fact that doctors as well as patients might

estivate. Not all city doctors go to Europe every summer. The baser sort go into the back districts of their own beloved land as cottagers, the refuse and offal even as boarders, and in their villeggiatura keep one eye open on the main chance. The urban patient prefers them to the rural practitioner. The very country doctor's own rural patients in some cases exhibit a preference for the treatment of the visiting city practitioner.

"Our own sympathies are distinctly with the country doctors, who are entitled to share the general perquisites of their neighbors, and against the city doctors, who ought to be improving their game of golf or imbibing the beauties of nature instead of healing the sick

or burying the dead."

# MEDICAL PROGRESS

Treatment of Chronic Rheumatic Affections by Paul's Cutivaccine.-Dr. F. Ferrière of Geneva reviews the various therapeutic methods in vogue in the so-called rheumatic affections-by drugs, the salicylates, sulphur, iodine; balneotherapy; parenteral protein injections, and bacterial vaccines. All of these methods are more or less useful, but leave much to be desired in individual cases and are not universally applicable. He then describes the cutivaccination method introduced by G. Paul and first described in the Wiener medizinische Wochenschrift, No. 14, 1927. It is based on the theory of a special function ascribed to the skin of dissociating certain antigens and causing a local and general reaction. This led to a search for a special vaccine which would exert a sufficient stimulation of the skin without causing an injurious general reaction. After many trials he devised the following: (1) Weleminsky's tuberculomucine, the great advantage of which is that it causes a good local reaction but very little general or focal; it is a protein extract of the tubercle bacillus with the exclusion of the virulent principles -of these microorganisms; (2) The product of filtration in vacuo of a bouillon culture of a group of saprophytic organisms; (3) Cowpox vaccine freed from all living germs; (4) A minute quantity of Koch's tuberculin. This cutaneous protein therapy acts by producing various stimulating products which are obsorbed by the lymphatics very slowly and excreted very slowly, thus ensuring a prolonged action on the organism. The scarifications should be superficial, involving the epidermis only, they should not be deep enough to cause bleeding, and the vaccine should be rubbed over the scarified part for two or three minutes with the flat of the lancet, the skin being stretched between the thumb and index finger. The general reaction is as a rule light-little more than a slight feeling of fatigue or aching of the muscles of the back and possibly a moderate elevation of temperature for a few hours. For mild cases five or six vaccinations will usually suffice, for severe and inveterate cases ten or fifteen or even twenty vaccinations may be called for. In considering the results of the vaccination treatment the author groups his cases in four categories based mainly upon the gravity of the lesions, (1) Chronic muscular and articular rheumatism of mild degree (without any joint deformities): 32 cases, the number of vaccinations varying from three to ten, giving 75 per cent of improvement. Though the good effects had lasted two years the author refrains from speaking of a cure in view of the ever-present fear of relapses. (2) Chronic rheumatism with slight articular or periarticular deformity: 14 cases, 6 to 18 vaccinations each, 50 per cent improved. (3) Chronic deforming and ankylosing rheumatism: 5 cases, 12 to 20 vaccinations, 1 case very markedly improved after the sixteenth vaccination, the others relieved as regards pain, but with only temporary functional improvement or none (4) Rheumatic neuralgias (sciatica, intercestal and trigeminal neuralgia, etc.): 9 cases, 3 to 10 vaccinations, the results being variable in cases symptomatically similar; in general 60 per cent were improved.—Schweizerische medizinische Wochenschrift, July 12, 1930.

The X-Ray Treatment of Chronic Arthritis. -In a paper read before the XIV Northern Congress for Internal Medicine, Drs. G. Kahlmeter and A. Akerlund call renewed attention to the treatment of the various forms of chronic arthritis by means of the roentgen rays. This is not a novel treatment, for as long ago as 1897 Sokelow published a series of cases and Stenbeck also employed this form of therapy at the same period. Among the affections most favorably influenced by the x-rays are gonorrheal and acute and chronic infections arthritis, but even in arthritis deformans many claim that better results are obtained than by any other method. The first effect obtained is a diminution of pain, both spontaneous and that elicited by pressure and movement. The reduction of pain is often observed within a few days, but real improvement in the other symptoms is obtained as a rule only after some weeks, but then the betterment continues, sometimes for several months, after the treatment has been discontinued. The mode of action of the rays is not easy of explanation. Some regard the analgesic effect as the chief factor, whole others believe that the inflammatory fibrosis is softened by fibrolytic ferments set free by the disintegration of the leucocytes. But these and other theories, including that which regards the process as similar to that of non-specific protein injection, are not very plausible. The rays are given by the author in two or three series at intervals of one or two months, each series consisting of a couple of deep roentgen doses of medium strength applied from different aspects around the joint, one or two days intervening between each application. The radiated fields are, in the case of a knee or elbow, about one-quarter of the circumference of the joint in width and 15 cm in height first series, at the two applications made on consecutive days, the lateral aspects of the joint ne irradiated, and in the second series, four to eight weeks later, the rays are directed at both applications from in front and behind. In the third series (usually the last) coming after another interval of four to six weeks, the applications are made from the opposite sides as in the first series. Of 94 cases of various forms of arthritic rheumatoidal affections (including arthritis deformans gonorrheal arthritis, morbus coxæ senilis and other forms of monoarthritis and subacute gout treated by the authors (180 joints in all), a symptomatic cure was obtained in 42 joints (23 percent). improvement in 109 (60 percent), and no bene fit in 29 (17 percent) The largest group of cases comprised rheumatoid arthritis and arthritis deformans-34 cases with an aggregate number of 88 joints. Of those joints 10 were rendered free of symptoms, 65 were very manifestly improved, objectively and subjectively, and 13 showed no improvement. The main objection to this method of treatment is the danger of a too long continuance of the applications When more or less improvement has been obtained the patients often clamor for additional treatments, which cannot be given because of the danger of a-ray dermatitis -Acta Medica Scandinavica, Supplementum XXXIV

Intestinal Obstruction -A Primiose writes with special reference to the rôle played by the general practitioner, since prompt diagnosis of intestinal obstruction is of the utmost importance, and it is often within his power to overcome the patient's desire to avoid opera-Furthermore, he may assist materially in improving the patient's prospect of recovery by the administration of decinormal salt solution interstitially or intravenously. An obstruction high in the bowel is much more rapidly fatal than a low one The mortality of intestinal obstruction reaches as much as 60 per cent The death rate decreases in proportion to the time elapsing between the onset of symptoms and the employment of efficient treatment. As a cause of death toxemia may play a minor role the real cause of death being the loss of sceretions which fail to resorb There is a change in the blood chemistry producing an alkalosis. It is characterized by a fall in the blood chlorides and a rise in the carbon dioxide combining power of the plasma. If the chlorides fall below 0.45 mg per 100 cc of

blood, peristalsis is inhibited. The chlorides may be restored to normal proportions by the administration of chlorides by mouth, by the rectum, interstitially or intravenously, or by a combination of these methods Water and plucose are also of specific value By its diuretic effect, glucose aids in the elimination of non protein nitrogen and in furnishing energy Water replaces that lost by vomiting and prevents deliveration. Chlorides may be admin istered by rectum in the form of ammonium chloride, 180 grains in three ounces of water, every four hours Glucose, 10 per cent in physiological saline, may be administered interstitially or intravenously, in amounts of 600 cc Physiological saline solution may be pressed to the extent even of 5 000 cc in twenty-four hours Bicarbonate of soda increases alkalosis and predisposes to tetany, therefore, this drug must never be administered in intestinal obstruction The general practitioner should give this treatment without waiting for a blood examination Operation is, of course, absolutely necessary Enterostomy is believed by some authorities to be of great value, particularly if peritonitis is confined to the lower abdomen with spasmodic cramps or visible peristalsis The lowest mortality has been achieved under general anesthesia. Spinal anesthesia as a curative measure in paralytic ileus is undoubtedly of the greatest value in certain cases -Canadian Medical Association Journal, July, 1930, xxm, 1

Food Poisoning Due to Eggs -W M Scott calls attention to the fact that eggs, usually considered to be one of the most wholesome forms of food, are responsible for many cases of food poisoning which remain mysterious He describes a number of instances, affecting both single individuals and groups of people, the largest outbreak involving over 300 persons, with one death. The type of infection was that of B acttrycke and the evidence was convincing that the infection was conveyed by ducks' eggs There is a considerable literature on the subject In 1906, A Lecoq published a monograph in which he expressed the opinion that the infection was introduced into the oviduct of the duck or hen during the copulation Spencer Low suggests that infection of the egg with Salmonella could take place as a part of a general infection of the bird, such as has been assumed to occur in parrots with psittacosis Scott suggests that eggs may become infected by contact with

B acriryche if the shell is most An egg thus infected might not appear to be more than elightly stale. All eggs are not readily infected in this manuer. The duck's egg, however, has definite opportunities of becoming

infected in all three ways. It should not be used in any way in which thorough cooking is not involved. While the risk of food poisoning from this source is comparatively remote, it should be borne in mind in solitary cases of food poisoning, especially as the egg is one of the commonest and most conspicuously unshared of dishes in ordinary life.—British Medical Journal, July 12, 1930, ii, 3627.

Allergic Migraine.—Ray M. Balyeat and Fannie Lou Brittain present a study based on 55 cases of migraine, in 45.4 per cent of which a family history of allergy was elicited. There was a family history of migraine in 25, or 45.4 per cent; in 37, or 67.3 per cent, of the cases there were other manifestations of allergy, such as hay fever, eczema, urticaria, and asthma. From a study of the hereditary factor in migraine it seems logical to believe that the existing factor is always a specific sensitivity to one or more foreign proteins. The hereditary factor appears to be interchangeable in the linkage with asthma and hay faver, which is good evidence that these syndromes have a common etiology, namely, a specific sensitization. There are, however, many predisposing factors, such as physical fatigue, mental fatigue and depressed states, thyroid dysfunction, toxic states, and disturbances of the special senses. Most patients with migraine are sensitive to a multiplicity of proteins. The onset of symptoms occurred in nearly one-third of the cases during the first decade of life. The persistence of migraine symptoms up to and through the sixth dec-. ade of life is not uncommon. These patients are usually above the average both mentally and physically. In the treatment predisposing factors should be eliminated as well as all foods and dusts to which the patient is found specifically sensitive. In the author's series of 55 cases, 29 or 52.7 per cent, obtained from 85 to 100 per cent freedom from symptoms. Only five patients received less than 40 per cent, or no relief. It thus appears that the results in the treatment of migraine are as good or better than those obtained in nearly any other chronic disease.—American Journal of the Medical Sciences, August, 1930, clxxx, 2.

Treatment of Hay Fever.—Dr. Ch. Flandin of Paris, writing in The Bulletin Médical, July 12, 1930, xliv, 30, expresses scepticism as to the allergic origin of hay fever. Cases are not infrequent, he says, of spasmodic coryza lasting the year round with exacerbations in the spring and autumn, and such cannot be caused by pollen since they continue at a season when no pollen exists. This reasoning is not altogether convincing since it rules out

only one form of allergic causation. The author also disputes the reliability of the cutireaction, for treatment based upon such reac-. tion is not always successful. He recalls a case in Widal's clinic of a beggar suffering from some supposed allergic trouble who was submitted to a long series of tests with negative results and finally reacted to caviar, a substance he had never tasted and did not even know what it was. Every year, the author says, he sees a great number of patients treated secundum artem with ten to twenty prophylactic injections of the indicated pollen who keep on sneezing just the same. Perhaps they sneezed even more for it is not improbable that in some the injections were productive of sensitization. In place of this treatment Flandin employs a method of autoserotherapy employed by Achard and himself since 1913. It is advisable to give a very small dose—not more than 0.1 to 0.3 c.c. injected intradermically. Thus enough blood may be obtained at one time to serve for a three weeks' course of treatment. Thanks to this therapy, the course of treatment being repeated if necessary several years in succession, the author has permanently cured a number of hay-fever patients who had received a great number of so-called specific intradermic injections without benefit.

Clonic Spasm of the Eyelids in Epidemic Encephalitis.—Dr. C. T. Manthos of Salonica reports two cases under his observation in the Military Hospital. In one case the patient, 21 years old, had a tremor with some rigidity of the left side and was markedly somnolent, with the face immobile and without expression. The trouble had started six months before with a fever of 39° C. (102.2° F.), somnolence, and temporary diplopia with sialorrhea. When told to close the eyes forcibly, the lids became affected with intense clonic spasms lasting as long as they remained closed. In the second case, a Greek, 17 years old, had been taken with fever, an epileptic paroxysm, somnolence for about two weeks followed by stiffness and numbness of the right arm and leg, nystagmus, and subjective sensations of light. There were no evidences of cerebral hypertension, there was no dysarthria, and the spinal Wassermann test was negative. In this case also as soon as the patient closed his eyes there was evident a rapid clonic tremor which continued until the man was told to open them. In general the author said he had noted this very exaggerated clonic spasm of the eyelids in all cases of epidemic encephalitis and of the parkinsonian post-encephalitic syndrone,-Bulletin de l'Académie de Médecine, de Paris, July 8, 1930.

Arterial Pressure in Its Clinical Aspects .-In reviewing the subject of high blood pressure, J. F. Halls Dally emphasizes the importance of the diastolic pressure, since it is a measure of the burden which the arterial walls and aortic valves must continually bear, while the systolic pressure represents only an intermittent and superadded load. Drastic attempts to reduce the blood pressure should be avoided. Since toxemia, worry, and excesses of various kinds are the most potent causes of high blood pressure, they should first be eliminated. Tobacco should be avoided and moderation in all things enjoined. Deep breathing exercises, relaxation, passive movements, resistance exercises, and massage have their appropriate The x-rays, high frequency, and diathermic currents in experienced hands yield good results. In threatened or actual apoplexy lumbar puncture is of timely aid. Venesection up to 500 c.c., followed by fasting for a couple of days, gives relief to an embarrassed circulation, particularly in the presence of venous stasis. For the toxemia resulting from intestinal stasis rectal injections every morning for three weeks of a solution of potassium permanganate, one grain in a pint of water, is often of great value, constipation at the same time being corrected by tablets containing bile Calomel at night twice weekly, in 2grain doses, with a teaspoonful of equal parts of sodium and potassium sulphate on the morning following, is useful in thinning the bile, and by thus inducing a greater flow lessens intestinal putrefaction. In the lesser grades of hyperpiesia potassium chloride in two-drachm doses three times daily gives encouraging results. For the cardiac types theominal, a combination of luminal and theobromine, promotes diuresis and lowers arterial pressure. Iodine is of little use, greater effect being obtained by the administration of the French tincture, 5 minims in milk or water after meals, gradually increasing the dose. More recent. remedies are: (1) liver extract; (2) sodium sulphocyanate, in three-grain tablets by mouth; (3) choline derivatives, and (4) endocrine preparations. Manipulations, baths, and douches are beneficial in high pressure cases, and in those of low pressure associated with circulatory stasis .- British Medical Journal, July 5, 1930, ii, 3626.

The Fibroses of the Heart.—John Cowan discusses fibrosis of the heart due to myocarditis, ischemic necrosis, and syphilis. In acute myocarditis the lesions are small, usually consisting of round celled infiltration of the tis-

sues. They are generally situated in the walls of the ventricles, especially the left, and often in the vicinity of, or around, an arteriole. Of the ischemic fibroses, a large group are caused by interference with the blood supply through the coronary arteries. If the closure of a blood vessel is sudden, necrosis results, with later infarction. The most important and the most frequent sequel of syphilis is disease of the coronary arteries and ischemic fibrosis. In ischemic disease of the myocardium pain is often a striking symptom, the onset is sudden, and the most serious symptoms immediately precede death. In acute myocarditis pain is exceptional, the onset is generally insidious, and serious symptoms may occur early in the illness. The symptoms are often masked by the primary illness, and can only be differentiated with difficulty. Acute myocarditis is most common in cases of acute endocarditis. In a few cases the occurrence of a nodal rhythm, or progressive cardiac failure without obvious cause, affords presumptive evidence of its presence. In ischemic fibrosis the symptoms may be those of angina pectoris; of congestive heart failure, of either sudden or of insidious onset; of disturbance of cardiac rhythm, the most common being heart block; or the signs may be those of disease in organs other than the heart, cerebral symptoms being most common. Angina, apart from aortic valvular disease, pregnancy, operations, or severe anemia, indicates interference with the coronary blood supply, and hence a potential or actual fibrosis. Infarct, heart block, and bundle branch block are also indications of fibrosis. A symptom not uncommon in infarct is pain not infrequently referred to the abdomen and associated with gastric symptoms. The changes in the electrocardiogram in myocardial infarct have been studied, but accurate deductions are not yet possible. The early changes are usually shown as a deviation of the R-T segment from the iso-electric level. The deviation may be upward or downward, the direction in Leads I and III being opposed. In the course of a few days the curve alters: negative T waves appear, running out of QRS without any iso-electric period. The subsequent changes are in the direction of normal. The issue in acute myocardial disease, whether inflammatory or ischemic, depends upon the treatment of the initial attack. The only safe plan is to maintain rest for several months after the acute symptoms have passed. The rest must be absolute at first. Restlessness must be combated by sedatives .- The Lancet, July 5, 1930, cexix, 5575.

# INSURANCE POLICY - DISTINCTION BETWEEN ACCIDENT AND DISEASE

By LORENZ J. BROSNAN, ESQ. Counsel, Medical Society of the State of New York

An interesting decision of our Court of Appeals involving a construction of an insurance policy was recently handed down by the court.

The defendant Insurance Company had insured the plaintiff's husband against the result of bodily injuries "Caused directly and independently of all other causes by accidental means," the insurance in the event of his death to be payable to his wife. The policy was not to "cover accident, injury, disability, death or other loss caused wholly or partly by disease or bodily or mental infirmity or medical or surgical treatment therefor."

The insured, while lifting a milk can into an ice box, slipped and fell, the milk can striking him on the abdomen and causing such pain that he was unable to get up. A physician was called who advised an immediate operation. Upon opening the abdomen, the surgeon found a perforation at the junction of the stomach and the duodenum, through which the contents of the stomach escaped into the peritoneum, causing peritonitis and, later. death. At the point of the perforation there had been a duodenal ulcer, about the size of a pea. Evidence in the case showed that the existence of this ulcer was unknown to the insured, and were it not for the blow, would have had no effect upon his health, for it was dormant, and not progressive. But, of course, there had been a weakening of the wall in some degree, with the result that the impact of the blow was followed by perforation at the point of least resistance.

The Insurance Company refused to pay the amount of the policy contending that death was not the result of an accident to the exclusion of other causes. The plaintiff received a verdict for the full amount in the court below, and this finding was affirmed by the Court of Appeals. The Court of Appeals pointed out that the ulcer was not a disease or infirmity within the meaning of the policy, since left to itself it would have been as harmless as a pimple or a tiny scratch. The Court further held, that the ulcer being dormant was incapable of becoming harmful except through catastrophic causes, not commonly to be expected, and that something more must be shown to exclude the effects of accident from the coverage of a policy of this kind. The disease or the infirmity must be so considerable or significant that it would be characterized as disease or infirmity in the common speech of men. The Court further held that "a policy of insurance is not accepted with the thought that its coverage is to be restricted to an Apollo or a Hercules."

The Court further pointed out that a distinction must be drawn between a morbid or abnormal condition of such quality or degree that in its natural and probable development it may be expected to be a source of mischief in which event it may fairly be described as a disease or an infirmity, and a condition abnormal or unsound when tested by a standard of perfection, yet so remote in its potential mischief that common speech would call it not disease or infirmity, but at most a predisposing tendency. To illustrate these principles, the Court pointed out that under a policy of this kind there could be no recovery if an everyday act, involving ordinary exertion, brings death to an insured because he is a sufferer from heart disease. While, on the other hand, a recovery will not be denied to the sufferer from hernia who has had a predisposition to rupture because the inguinal canal was not closed as it ought to have been, or to one whose hip has been fractured because his bones have become brittle with the advent of old age.

In laying down the principle which must govern in construing a policy of this character, the Court said:

"If there is no active disease, but merely a frail general condition, so that powers of resistance are easily overcome, or merely a tendency to disease which is started up and made operative, whereby death results, then there may be recovery even though the accident would not have caused that effect upon a healthy person in a normal state."

An ulcer as trivial and benign as an uninfected pimple, is at most a tendency to an infirmity, and not an infirmity itself.

Any different construction would reduce the policy and its coverage to contradiction and absurdity. The infinite interplay of causes makes it impossible to segregate any single cause as operative at any time and place to the exclusion of all others, if cause is to be viewed as a concept of science or philosophy The Courts have set their faces against a view so doctrinaire, an estimate of intention so headed toward futility. "We are to follow the chain

of causation so far, and so far only, as the parties meant that we should follow it: "The causes within their contemplation are the only causes that concern us."

### CLAIMED FAILURE TO REPAIR LACERATION SUSTAINED DURING DELIVERY

In this case the patient appeared at a charitable maternity institution and requested that she be placed upon the hospital service for care and treatment. She was examined by the defendant physician and gave a history of chronic appendicitis and irregular menstrual periods; excessive vomiting due to pregnancy; weakness, insomnia and nervousness Examination revealed a low blood pressure,-90 systolic, measurements slightly below normal; fetus in good position. The patient was in about the sixth month of her pregnancy. She was examined regularly thereafter at two week intervals on which dates treatment to which the patient responded satisfactorily was prescribed.

About three months after the first examination she was admitted to the maternity institution and examined by the house doctor who found her to have irregular pains with one finger dilatation. A hypodermic of morphine was administered. Several hours later when the patient was examined by the defendant she had had no pain since the administration of morphine and made no progress in labor. Then hours afterwards she was again examined but still had no pains and showed no progress in labor. She was then permitted to go home.

The following day she again called at the institution complaining of irregular pains. The house doctor again examined her and this time found a dilatation of two and one-half fingers. Several hours later when the defendant examined her, he found her to be in the same condition. That evening she ruptured her membranes spontaneously.

The morning of the following day the patient was found to be nervous, exhausted and suffering pains, rapid fetal heart; the fetal head not in complete rotation. Measures were taken to rotate the head slightly with forceps, and to aid the termination of the labor slightly. The forceps were used for a few minutes, sufficiently to rotate the head in the proper axis, and it was deemed wise to permit a spontaneous delivery. The patient was placed in bed and three hours later was permitted to walk about in order to increase her pains. A half hour after she had been permitted to walk about, without permission she walked out of the hospital. However, a nurse observed her and approaching her on the sidewalk brought her back to the institution, this being done with a great deal of difficulty because the patient became in sterical and cried that she wished to leave the hospital and refused treatment.

After a little time elapsed the patient quieted down, but in another half hour she again attempted to elude the nurses and leave the hospital. She was thereafter given a hypodermic of morphine. The same morning the patient delivered herself spontaneously of a baby girl. The placenta was expelled intact There were no apparent lacerations or other injuries that required immediate repair, and as the patient was greatly exhausted from tedious labor and her attempts to leave the hospital, it was deemed wisest to promptly place her in bed with as little manipulation and irritation as possible.

That evening the patient had a slight rise in temperature and thereafter ran a low grade infection temperature for about a week, the highest point being 102 F. The temperature, and all subjective and objective symptoms were treated in accordance with the most modern scientific methods. The patient made a good recovery and two weeks after the delivery was discharged from the hospital with a normal temperature and only slight abdominal pain on pressure. At the time of her discharge her breasts were normal, nipples normal, perineum good, cervix slight bilateral tear, uterus involuting, adnexa painful to pressure, with plastic exudate present.

On each day after the delivery she was examined and treated by the defendant physician

Some two and one-half years after the patient was discharged from the hospital, she instituted an action against the physician who had delivered and treated her, charging that he did not use due or proper care and skill in the confinement and delivery; that he permitted her to be discharged from the institution without certain necessary stitches for her laceration, by reason whereof she claimed to have sustained certain permanent injuries and her health became irreparably damaged. Since the action was commenced more than two years after the last date of treatment the complaint was dismissed on motion under the Statute of Limitations, thereby terminating the action in the doctor's favor without a trial.

# NEWS NOTES

## CONFERENCES OF COUNTY REPRESENTATIVES

Two important conferences of representatives of the County Medical Societies of New York

State will be held during September.

Secretaries' Conference: A meeting of the Secretaries of the County Societies has been called for Tuesday, September 9, 1930, at ten o'clock in the morning, in Albany. This conference is called in accordance with the action of the House of Delegates recorded on page 783 of the Journal of July 1. The expenses of the secretaries attending the conference will be paid by the State Society.

The custom of holding conferences of County Secretaries is widespread. The American Medical Association sets the example by holding an annual conference of the secretaries and editors of the several state societies in November; and several state societies hold conferences of the secretaries of their constituent county societies. This Journal, for example, on May first, 1930, printed an account of the annual conference of the county secretaries of New Jersey, abstracted from a seventeen-page stenographic report in the Journal of the Medical Society of New Jersey. This Journal on September 15, 1929, page 1164, printed an abstract of the twenty-first annual meeting of the Missouri Society of Medical

Secretaries, at which forty-two secretaries were present.

Several conferences of the County Secretaries of New York have been held. The last one was held in Albany on September 15, 1927, and was reported in the Journal of October 1, 1927, page 1094. This last one was of unusual interest and practical value.

Conference of Chairmen of County Public Relations Committees: A meeting of the Chairmen of the County Committees on Public Relations has been called for Thursday, September 18, ·1930, in Albany. This will be the first meeting of the County Chairmen of the whole State, but the need for it is real. Last fall Dr. James E. Sadlier, Chairman of the State Committee on Public Relations, adopted the policy of calling together the Chairmen of the County Public Relations Committees of each district at the time of the annual meeting of the district. These conferences showed that not only must the county leaders be instructed what to do, but also many must be told how to do it. The experiences gained in the fall conferences is a guarantee that the conference on September eighteenth will be of great practical value.

# THE OYSTER INDUSTRY

The interdependence of business, science, and government is illustrated in the shellfish industry, and was emphasized in a striking way by the speakers at the joint session of the Oyster Growers and Dealers Association of North America, Inc., representing the business interests of the shellfish industry, and the National Association of the Shellfish Commissioners, representing the governments of the United States and of the several States in which shellfish are produced. Over one hundred representatives of these two organizations met in Sayville on August 19-21, in perfect harmony, and discussed practical problems involving investments of millions of dollars and an important food used throughout the land. The predominance of sanitary problems makes the sessions worthy of reporting in the NEW YORK STATE JOURNAL OF MEDICINE. This report will be an attempt to outline the broad features

of the shellfish industry as it exists in the Eastern Coast of the United States today. While the principal shellfish is the oyster, the same principles apply also to the hard clam, the soft clam, the escallop, and the mussel, all of which grow under the same conditions as the oyster.

Oysters formerly grew naturally in nearly every bay and estuary of the coast in incredible profusion, and could be picked up by the basketful by children wading, or raked up by the boatload from deeper water. Both the supply and the demand seemed to be inexhaustible up to the middle of the decade of the eighties when the demand led the oysterman to substitute mechanical dredges for hand power in catching oysters, with the result that the bay bottoms were swept clean not only of oysters, but also of shells and other material to which the growing oyster must cling during an early stage of its growth. Moreover, the lack of adult oysters

reduced the spawn to an amount insufficient to replant the bay bottoms. The result has been that the individual oysterman working by hand could not make a living, owing to the prevailing American custom of exhausting all our natural resources.

Today the great bulk of oysters on the market are produced on "farms" which are tended and watched as carefully as those of the market gardener. The oyster grower buys his "seed," cultivates his crop for two or three years, and finally prepares it for market with the precautions and care that are used in the marketing of milk.

It happened that bays and estuaries were the haunts of men as well as oysters, and their shores were the sites of villages and cities whose people poured their wastes into tidal waters. Human wastes contain disease germs, and industrial wastes often include poisons which are deadly to oysters. Hundreds of square miles of rich oyster grounds in the vicinity of populated centers have been condemned by the health authorities, but thousands of miles are still safe grounds for shellfish cultivation.

One of the great problems of the oyster growers is to secure the lease of the oyster grounds from the states and municipalities which own them. These grounds are of two kinds:

1. The natural beds where the oysters grow and multiply spontaneously.

2. The areas on which young "seed" oysters will flourish when they are simply thrown overboard.

It seems an incredible state of mind that the "poor" oysterman and all his relatives should . object to the lease of bottoms which cannot be of use to him; and yet he is often able to hold up legislators and prevent them from leasing the planting grounds to those who are financially able to cultivate them. Fortunately the States of New York, Connecticut, Rhode Island, and New Jersey make provision for leasing ovster grounds.

Oyster growing under modern conditions requires scientific knowledge and practical experience of a high order. Oyster marketing requires a uniform system of sanitary inspection, and governmental enforcement of rules. All oyster growing States therefore have shellfish commissions; but their work is unified by the United States Public Health Service, acting under the authority of Federal Interstate Commerce law. The dual system has been developed and coordinated so that the Federal officers supervise the sanitary inspections of the grounds and packing houses, and set the standards for their sanitation; and the authorities of the States, counties and cities enforce a conformity to the standard requirements. New York City also maintains its own system of inspection, certification, and enforcement, these requirements are respected by the oyster growers who are engaged in interstate commerce,-and that means practically all.

The first day of the Sayville session was devoted to discussions which were largely of a scientific nature. The program of the day was

as follows:

ington, D. C.

"Research Program of the Association," Dr. Herbert D. Pease, New York.

"Results of Oyster Market Survey," J. M. Lemon, U. S. Bureau of Fisheries, Washington, D. C.

"Export Possibilities of Oysters," R. S. Hollingshead, Foodstuffs Division, Bureau of

Foreign and Domestic Commerce.

"The Trade Journal and the Oyster Industry," J. E. Munson, Editor, "Fishing Gazette."
"Chemistry of Setting of Oysters," Herbert F. Prytherch, U. S. Bureau of Fisheries, Wash-

"Purification of Clams," L. M. Fisher, U. S.

Public Health Service, New York, N. Y. "Effects of Sulphite Mill Waste on Oysters," Q. E. Hopkins, U. S. Bureau of Fisheries, Washington, D. C.

A Preliminary Report on Studies of Larval Oysters as a Guide to Shelling Operations (illustrated with lantern slides), Professor Thurlow C. Nelson, N. J. Oyster Investigation Laboratory.

"Methods for Control of Starfish," Miss Louise Palmer, U. S. Bureau of Fisheries.

Washington, D. C.

"Control of Shellfish by Federal Departments, R. E. Tarbett, U. S. Public Health Service.

Washington, D. C.

"How the College Can Aid the Oyster Industries," Dr. Donald W. Davis, University of William and Mary, Virginia. Discussion by Prof. Frederick P. Gorham, Brown University, Providence, Prof. R. V. Truitt, University of Maryland.

"Oyster Growers' and Dealers' Association Research Committee," Dr. Herbert D. Pease, Pease Laboratories, Inc., New York, N. Y.

"Regulatory Measures of Cincinnati and Food Value of Oysters in the Diet," Dr. William H. Peters, Health Commissioner, Cincinnati, Ohio, Member of Sanitary Control Committee Shell-fish Industries of U. S.

"What the States Are Doing to Develop the Oyster Industry" (Round-Table Discussion participated in by leading executives from each

state represented).

"The Future Marketing of Oysters," William H. Raye, President, General Scafoods Corporation, Boston, Mass.

Moving Michrophotos of Spawning of

Oysters, Development of Oyster Larvæ and Setting. Also Special Film Showing Growing of Artificial Pearls in Japan.

Wednesday was spent in an inspection of the plant and grounds of the Blue Points Company at West Sayville. Here the Oyster Growers and Dealers Association maintains a research laboratory for the investigation of problems connected with the spawning of the oyster and the development of the spawn, the purification of the oysters, and their bacteriology, and the methods of preparation for shipment. This work is in charge of Dr. Herbert D. Pease, of the Pease Laboratories of New York City.

Thursday was spent in a trip to the oyster grounds at Greenport, where conditions are different from those at Sayville.

Confidence in the wholesomeness of oysters in the market, like that of milk, is dependent on the high standards and character of the producers and dealers. The brands of the well-known oyster companies are like those of the milk companies, and are equally reliable. Any one wishing to know the quality of oysters in his town can obtain reliable information from his Board of Health.

This Journal will publish articles on oyster sanitation in the near future.

# COMMENTS ON A NATIONAL MATERNITY SERVICE SCHEME FOR ENGLAND

This article is the fourth of a series of abstracts on English medical service.

The British Medical Journal of August 9, 1930, page 223, contains an abstract of a report of the Departmental Committee of the Ministry of Health on the subject of maternal mortality and morbidity, commenting on the British Medical Association's plan for a National maternity service, an abstract of which was printed on page 1000 of the New York State Journal of Medicine of August fifteenth. The proposals of the Association were not adopted by Parliament, but the Ministry of Health made extensive studies during the past year, and issued a report which filled 151 pages. The Journal states:

"The committee desired to base its report upon an examination of a sufficient number of maternal deaths of which reports had been made by an experienced medical officer in each sanitary area in accordance with an arrangement entered into in the early part of 1928. The drafted form of inquiry in connection with this arrangement, which received the concurrence of the British Medical Association under conditions safeguarding the confidential nature of replies thereto, was issued in October of that year, and the main part of the departmental committee's report is based upon a careful examination of the first two thousand cases of which particulars have thus been obtained. The two thousand maternal deaths which were investigated were unselected cases, probably representative of the deaths occurring all over the country. They are classified in a way which has much practical value, and the conclusions which are drawn from them are expressed very carefully and with a commendable absence of dogmatism."

The committee divided the maternal deaths into two classes, as follows:

"(1) Deaths directly due to pregnancy and

child-bearing, including abortion and ectopic gestation, 1,596 in number.

(2) Deaths due to an independent disease concurrent with pregnancy or child-birth, 404 in number."

The cause of deaths in class one are given as follows:

"In the first class, 38.6 per cent of the deaths were due to sepsis, and 13.6 to eclampsia, while shock, ante-partum and post-partum hæmorrhage, other toxæmias, and embolism were responsible severally for percentages varying between 6 and 9."

Sepsis caused 616 deaths, whose causes were classified as follows:

Following ordinary normal labor, 294 cases.
 Following delivery by low forceps in an otherwise normal labor, 47 cases.

3. Following complicated labor, 275 cases.

The report continued:

"The main object of this investigation was, of course, not academic but practical. The investigators, have accordingly fried to discover in each case what they call the 'primary avoidable factor'-that is, the first omission, mistake, or misjudgment in the train of events which led up to the fatal result. The standard of comparison on which judgment was based is set out. It is not an unduly high one, but rather one which may reasonably be expected to be attained in good medical practice in most parts of the coun-Omitting cases of abortion and of extrauterine gestation, and a number of others in which information was insufficient, the cases which showed a primary avoidable factor were 626, and those in which no departure from established practice having a causal relationship with the death was found were 660. In a broad

general analysis, therefore, and with no claim to mathematical accuracy, it may be said that the net percentage of preventable deaths is as high as 48. The primary avoidable factors in these 626 cases are subdivided under four headings

(1) Omission or inadequacy of ante-natal examination, 226 cases.

(2) Error of judgment in management, 224 cases.

(3) Lack of reasonable facilities, 64 cases

(4) Negligence of the patient or her friendsusually in failing to follow the doctor's advice or in ignoring obvious and serious symptoms, 112 cases.

"In the first two of these groups the doctor, the midwife, the hospital, or the clinic may have been at fault, and the first group contains 109 cases in which the pregnant woman did not submit to ante-natal examination. These

are not included in group four.

"The committee realizes that caution must be exercised in drawing conclusions from the evidence obtained from these investigations, but it is clear that information has been elicited which is of definite and substantial practical The vast importance of adequate antenatal examination and supervision in every case is reaffirmed, and adequate treatment of any discovered abnormality should naturally, but does not always, follow.

"Amongst the deaths from hæmorrhage, a number of patients might have been saved had specialist services, including facilities for blood transfusion, been at hand. At the same time it must not be lost sight of that the majority of cases of hæmorrhage and obstetric shock can be saved from death by the immediate replacement of fluid by intravenous or subcutaneous saline solution. Attention is drawn to the relative infrequency with which this treatment is adminis-

"With regard to sepsis, substantial improvement may be looked for when ante-natal diagnosis becomes more efficient and widespread, when a specialist service is more easily obtainable, and when hospital accommodation for suitable cases is more adequate. Even so, the number of deaths from sepsis following 'normal labor' demands

intensive investigation.

The abstract in the British Medical Journal makes brief comments on the reports on puerperal Concerning anæssensis and ante-natal care,

thetics the abstract says:

"Other very important and valuable chapters of the report deal with the use of anæsthetics and analgesics in obstetric practice, with medical education in obstetrics, and with a national maternity service. On the first of these subjects three interesting memorandums are given in appendixes—one from the Royal College of Physicians of London, one from the British College of Obstetricians and Gynecologists, and one from the British Medical Association. This last is printed in the Annual report of Council (Supplement, April 19th, p. 163), and was approved by the Representative Body last month perhaps the most emphatic of the three with regard to the use of anæsthetics and analgesics by anyone other than a registered medical practitioner; but the three pronouncements are in substantial agreement, and the committee does not differ from them in their conclusions"

Commenting on anaesthetics, the British Med-

ical Journal, page 218, says editorially:

"The Departmental Committee on Midwives said that 'it would be to the public interest if some professional body would issue at an early date some pronouncement as to the advisability and place in labor of anæsthetics and sedative drugs generally.' In response to this the Council of the Association set up a special committee to report on this matter, and this report was submitted to the departmental committee. were similar reports from the Royal College of Physicians and from the British College of Obstetricians and Gynecologists. Meanwhile a well-intentioned but misguided effort had been publicly made to provide anæsthesia for every maternity case. All the reports referred to point out the undesirability of these drugs in certain classes of cases and the danger, either to mother or child, of their use by persons other than properly qualified medical practitioners. The committee's report fully endorses the position held for so long by the British Medical Association; nevertheless, the provision for anæsthesia is an essential part of any national maternity service."

The abstract closes with comments on the edu-

cation of physicians as follows:

"In regard to medical education, the most important suggestions of the committee are:

(1) That the statements of the requirements of the General Medical Council should be made

more clear and definite;

(2) That the time given to midwifery and gynecology (including infant hygiene) should be doubled-six months' whole-time hospital practice, including two months' residence in a maternity hospital.

(3) That the number of labor cases personally attended (in the suggested alteration 'attend and personally deliver') shall be thirty instead of

twenty;

(4) That ante-natal instruction shall entail the personal examination, under supervision, of not less than fifty pregnant women;

(5) That there shall be at least eight attend-

ances at an infant welfare centre;

(6) That priority shall be given to the medical student over the student midwife in maternity hospitals, or possibly that students and midwives shall be educated together in this respect."

# THIRD GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The New York Academy of Medicine is a center of medical information along all linesscientific, literary and historical, public health, and popular health education. It is a clearing house of information regarding hospitals, and the operations and clinics held in them. Its medical library is one of the largest in the country and is open to physicians generally. If a reader wishes a copy of an article, he may have a photostat of the article, including its illustrations, done for less than the cost of typing the article.

Election to membership in the New York Academy of Medicine is an honor to any physician, but generous endowments make it possible for the Academy to extend its benefits to physicians generally. Visiting physicians are invited not only to share in the professional benefits of the institution, but also to make the building, at 2 East 103rd Street, their headquarters where they may have their mail sent and where they may make appointments to meet their families

and friends.

Two years ago the Academy extended its system of medical instruction by providing a twoweeks' series of clinics and lectures called The Graduate Fortnight, on the general subject of the Diseases of Old Age. Its success encouraged the officers of the Academy to repeat the plan of the courses in 1929, taking as its general subject "Functional and Nervous Problems in Medicine and Surgery." The afternoon clinics in 1929 were crowded to overflowing and the average attendance at the evening lectures was 545 by actual count.

The Graduate Fortnight will be repeated this year on the general subject "Medical and Surgical Aspects of Acute Bacterial Infections." The committee in charge of the Fortnight consists of Dr. Harlow Brooks, Chairman, with Drs. F. W.

Bancroft, Ludwig Kast, Emanual Libman, and H. F. Shattuck his associates.

The dates are two weeks in October from the 20th to the 31st, inclusive. The clinics will be held on afternoons, and lectures in the evenings.

The places are:

The amphitheatres of ten of the largest hospitals in the city, for the afternoon clinics.

(b) The large Assembly Hall of the Academy

for the evening lectures.

The price,—free. The Fortnight is the contribution of the Academy to the medical profession. The only restriction is that tickets, which may be obtained at the Academy, will be required for the afternoon clinics, owing to the limited capacity of the amphitheatres in which they will be held.

An added feature of the Graduate Fortnight this year is an exhibit of research material and s pecimens,—anatomical, bacteriological, and pathological,—of infections. This exhibit will be

held in the Academy Building.

The plans of the Fortnight leave mornings free for the usual operative clinics which are held daily in the hospitals, and to which visiting physicians are cordially invited. The Academy keeps an up-to-date list of the clinics in all hospitals of the city, and publishes it in a daily Bulletin which will be sent free during the Fortnight to all who apply for it.

A 24-page folder has been prepared, giving an outline of every lecture and the details of the It lists 25 speakers on the evening programs, and 121 lecturers at the afternoon clinics. Copies of this folder have been mailed to every doctor in New York State, and also to all physicians in New Jersey, Pennsylvania, and Connecticut, within a radius which may be considered as the Metropolitan area.

### WINKS AND BLINKS—NO. 2

Four out of every five doctors have it-unpaid bills.

The late lamented Wall Street débâcle was especially hard on patients.

W. Somerset Maugham, a physician who adorns the ranks of modern writers.

Show me a man who never sought free advice from a doctor and I'll show you a man who never lived.

Why are ambulances not painted white?

Medicine: the most widely advertised—to profession.

One of the most successful builders of apartment houses in New York is a physician who gave up his profession because of the poor returns.

A veterinary's card in a garage.

The notoriously indifferent penmanship of doctors.

What to do with all the samples.

The indifference of most doctors toward communal affairs.

The geniality of some detail men.

President Hoover a specimen of robust manhood.

The radio challenges the cradle as a sleep disturber.

Because the source is a parrot, the name of the disease is polly-syllabic.

A backwoods hamlet wrought into a world medical Mecca by the Mayos.

### THE POWER OF SUGGESTION

From the New York Herald Tribune, July 23, 1930

Play consists at working hard at that which one likes to do. A vacation is often irksome because of a lack of anything to occupy the mind. August is the circus season when the height of a boy's ambition is to acquire the thrill which is suggested by the smile of the trapeze actor on the flaming poster.

The power of suggestion is one of the most potent impulses of human nature. It comes to life in the small baby, and it survives after other mental processes have decayed. Field day sports at State Hospitals often turn the insane into normal persons while they are competing; and inmates who have little interest in life boast of their prowess in their own special field. However, it is usually necessary to provide a prize for each contestant in order to avoid disputes as to the real winners.

## SHORT CUT WITH FINES

Some European countries permit a traffic officer to receive traffic fines from the offender. A somewhat similar plan is proposed for New York City according to the following editorial in the New York Herald Tribune of July 31st:

"The proposed short cut of fixed small fines, imposed by notification and payable at the City Chamberlain's office—in place of the familiar vexatious court process—for persons caught violating the noise and litter ordinances, seems a sensible arrangement, worth a trial. It has been carefully thought out. The plan, devised by Charles C. Burlingham, president of the Bar Association, and former Magistrate W. Bruce Cobb, and indorsed by the Police Commissioner, the Chief Magistrate, the Sanitation and Health Commissioners and the Noise Abatement Commission, cannot be dismissed as a hit-or-miss suggestion.

The backers of the scheme have confidence

in its educative value. It will encourage the systematic nabbing of offenders. A multitude of small fines in the regular course of business may be a more effective reminder, and in time dissuader, to the careless-minded than attempts by fits and starts to enforce the ordinances dealing with minor offenses and carrying misdemeanor penalties. If the person receiving notice of a fine demands his day in court he will get it, of course, but he will more likely prefer to pay his little bill promptly and take a receipt.

"If the proposed routine works out as expected it will be a time saver all around—to the police, to the magistrates and to the petty offenders themselves. It may seem illogical to set about reducing the noise and litter nuisance by making the legal liabilities less trying to all concerned. But facts make the theory plausible—an experiment promising enough to warrant the necessary amendment of the City Charter."

# WHY SOME DOCTORS' FEES ARE LARGE

The New York Sun of August 14 carried the following item and comment:

"WANTED: Medical secretary-stenographer; 30-35 years; must have had actual experience in personally setting large fees for physician

specialist of standing. 12 East 41st street.—The Herald Tribune.

The Sun comments:

"It takes practice and presumably lots of nerve."

### ELECTRIC MEMORY

The New York *Times* of August 19 reviews the ancient speculations on the nature of memory in an editorial commenting on Dr George W. Crile's paper before the American Philosophical Society suggesting that memory is electrical in nature. This idea is satisfactory to some persons, for electricity is even more mysterious than memory. The editorial will doubtless be accepted as scientific from end to end as it says:

"Our lay acquaintance with the radio enables us to understand that the organs supplied by nerves perform work identical with that which stimulated them, but it is not so easy to comprehend how it is that a record is made so perfect and durable on chemical compounds of potassium, sodium, phosphorus, calcium, etc., that the memories of childhood may be carried throughout life or be subject to variations or temporary obliteration.

"The explanation is that the electric charge so affects the brain cells as to form fibrillae and create a specific pattern which is reproduced when a like impact comes again. Since there is assumed to be the possibility of infinite pathways or lines of conductance, this assumption also provides for 'millions of separate and distinct actions or memory patterns.' Their infinitely fine organization accounts for their capacity, while their association assures the permanency of the patterns and yet allows the blending of memories.

"This theory 'brings memory under the dominion of the physical laws governing living matter and non-living matter.' And now we await eagerly scientific advice how the brain-cell electricity may be generated in sufficient voltage for our individual use so long as memory holds its seat."

### SLEUTHING FOR NOISE

The anti-noise campaign in New York City is producing good results which should extend to the rural sections of the State. The New York Herald Tribune of July 27 says:

"One hundred and ten men of good hearing, who have lent their ears to the city for eight days, walked the streets of New York City last night listening for unnecessary noises. They were all volunteers enlisted by the Anti-Noise Commission to put in eight hours a day until next Friday locating and reporting places which operate radio sets loudly enough to violate city ordinances.

"The ordinary citizen, even when he is annoyed by loudspeakers assailing his ears as he walks along a sidewalk, will hesitate to complain to the shopkeeper operating the radio. He is afraid of being insulted or laughed at, even though he has a perfect right to complain. That is why we have formed the new anti-noise squad, made up of men familiar with the city ordinances and devoid of timidity. They will report infractions of the anti-noise regulations to the police.

"A reporter accompanied one of the untimid noise detectors on his inaugural round last night. In 'radio row' along Cortlandt Street and in Church Street, once a bedlam of doorway amplifiers, the city's crusader found nearly all of the shops had either cut off their lottd speakers or toned them down so that they were not heard above the traffic in the street. Salesmen in the radio shops said they had been warned recently by the police.

"In Forty-second Street none of the six radio shops between Broadway and Sixth Avenue had their sidewalk amplifiers in operation. One salesman complained that since a passing patrolman had ordered him to 'cut out the noise,' his sales had decreased."

### **ENDURANCE CONTESTS**

Endurance contests of sitting are beneath consideration in the New York State Journal of Medicine, but the following opinion in the editorial column of the New York Herald Tribune of August 20th is worthy of perpetuation:

"'But how did the elder folk, who knew better, view such moistrosities?' grandfather demands. 'Did no one call the children to come and do their proper chores?' 'Oh, they were thrilled! There is always an enthusiastic gallery for endurance contestants.' 'Adults gather to watch children showing off? Then has no one any

work to do now?' 'Well, somehow they find time for big things like that.' 'Does life no longer provide responsibilities for all alike?' 'No, it provides leisure, but the people don't know exactly what to do with it yet.'

"Mastering his angelic emotions, grandfather here flicks an asphodel. 'There was no such problem in my day. Sitting, stranger, is an ominous symptom, except in hens. I could not have believed that "endurance" would ever mean sitting and dancing and eating pie. It used to mean pluck."

# BOOK REVIEWS

RECENT ADVANCES IN PULMONARY TUBERCULOSIS. By L. S. T. BURRELL, M.A., M.D. Octavo of 217 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, 1929. Cloth, \$3.50.

Here is an excellent little book covering in compact form and in clear and concise English most of the recent advances made in the study of Pulmonary Tuberculosis, particularly in the matter of treatment, though diagnosis and prognosis are by no means neglected. The book abounds in beautiful photographic reproductions of roentgenograms.

Many pages are devoted to Collapse Therapy and the numerous problems that arise in the course of its institution. These are all handled in a particularly able and conservative manner, especially those relating to the complications that arise in the course of artificial pneumothorax treatment. Passing mention is also made and a lucid description given of the intrathoracic cauterization of adhesions occurring in the course of pneumo-thorax therapy, known as the Jacobeus operation. Phrenicectomy is admirably presented—its indications, contra-indications, technique and results. A chapter or two is also devoted to thoracoplasty.

Dr. Burrell has evidently been much interested in Sanocrysin and has observed its effect on some sixty cases. These cases were all receiving rest therapy or artificial pneumothorax at the same time that they were under Sanocrysin. This should be borne in mind in attempting to evaluate the efficacy of Sanocrysin. It might be said in passing that enthusiasm for this particular mode of therapy has been on the wane during the past two years. FOSTER MURRAY.

CLINICAL MEDICINE FOR NURSES. By PAUL H. RINGER, A.B., M.D. Third Revised Edition. 12mo of 330 pages, illustrated. Philadelphia, F. A. Davis Company, 1929. Cloth, \$3.00.

This third edition has been brought up to date and presents the subject in 36 chapters, which are amply illustrated with charts, drawings and photographs. The common medical subjects are presented in clear, concise, simple language and in a most practical manner. A glossary of the common terms used will be found of considerable value.

H. M. Feinblatt.

Memoranda of Toxicology. Partly Based on Tanner's Memoranda of Poisons. By Max Trumper, B.S., A.M., Ph.D. Second Edition. 16mo of 214 pages. Philadelphia, P. Blakiston's Son & Company, 1929. Flexible leather, \$1.50.

This second edition of Dr. Trumper's excellent little book has been brought down to date, including such recent lethal substances as are found in modern refrigerating machines, etc. Essentially brief, it is remarkably complete and is probably the best short treatise on this subject that is available today.

We commend this volume as a necessary item in the make-up of a medical man's library. M. F. DeL.

THE CONQUEST OF CANCER BY RADIUM AND OTHER METHODS. By DANIEL THOMAS QUIGLEY, M.D., F.A.C.S. Octavo of 539 pages, illustrated. Philadelphia, F. A. Davis Company, 1929. Cloth, \$6.00.

Dr. James Ewing in an article on cancer as a Public Health Problem, published in "Health Reports" August 30, 1929, states that only within the past few years has cancer been considered as a public health problem. As a result in recent years instead of being entirely neglected by Health Departments throughout the country, there

has been quite a change in the attitude toward cancer. It remains clear then that we have a dual duty to perform, viz: first, the education of the lay public regarding cancer, and second, the education of the doctor. The former is being handled by organizations, as the American Society for the Control of Cancer, through lectures, literature, and various advertising features, the radio playing a very important part. For the latter, namely, the doctor, cancer clinics, numerous articles in medical journals, books, etc., are sources of information.

Cancer is still one of the most important subjects of discussion in medicine. The cause still remains in the realm of the unknown. Early diagnosis is the only hope for cure. Having made the latter, standardized treatment is then in order. Dr. Daniel Thomas Quigley in his book on "The Conquest of Cancer by Radium and Other Methods," can supply the accepted methods of diagnosis and treatment in a very brief and concise mandiagnosis and treatment in a very brief and concise man-ner, to members of the Medical Profession who have not kept up with the modern advances.

The accepted views as to the causation and prophylaxis are briefly outlined in the first part of the book and treatment in the remainder. Numerous illustrations, diagrammatic in nature, are represented which briefly explain the methods of origin, spread and actions of radium and x-ray.

The various subjects described are treated in a systematic way with an easy and pleasing style.

The book is far from being complete on the subject of Cancer but no book on this most disputed, unsolved subject can be. The book can be recommended highly for general practitioners and students of medicine. V. P. MAZZOLA.

THE SCIENCE AND PRACTICE OF SURGERY. By W. H. C. ROMANIS, M.A., M.B., M.Ch., and PHILIP H. MITCHINER, M.D. Second Edition. Volume 1, General Surgery. Volume 2, Regional Surgery. Two octavo volumes of 1,695 pages, illustrated. New York, William Wood & Company, 1929. Cloth, \$12.00.

This work appears in its 2nd edition in 2 volumes comprising 1,695 pages. The volumes are well bound, the paper is of good quality and the print is clear.

In producing this work the authors had in mind two

In producing this work the authors had in mind two main objects. In the first place it was written especially for medical students to use as a textbook and as a means of preparing themselves for surgical examinations. In the second place they kept in mind the medical practitioner that he might have a work of ready reference. The subject matter is handled rather uniquely. The human elements and the personal symptoms of the patients suffering from the diseases under discussion are given a rather prominent place.

At the beginning of many chapters there is a short account of the applied surgical anatomy and physiology of the region or organ to be discussed. The writers have also included several surgical procedures now obsolete, but which are of interest because of their classical associations. The technique of the operations is brief, the authors referring the reader to works devoted solely to technical surgery. There are several chapters devoted to the eye, ear, nose, throat, anesthetics, x-rays in diagnosis and treatment, and also to the surgical aspects of obstetrics and gynecology.

As a very comprehensive work for student surgeons and for a general surgical reference to be used by the practitioner of medicine, these two volumes are well recommended.

MERRILL N. FOOTE.

THE ESSENTIALS OF MEDICAL DIAGNOSIS. A Manual for Students and Practitioners. By SIR THOMAS HORDER,

Bart, and A. E. Gow, M.D. 12mo of 682 pages, illustrated New York, William Wood & Company, 1929 Cloth, \$500

The object of all teachers of this most important subject is to instill into the students the basic principles such as correct observation, complete and careful physical examination, accuracy in the use of medical terms and sound methods of inquiry

The authors have kept the above in mind and have presented in an original style and practical manner this

difficult subject

The subject matter is divided into eleven sections 1 Medical history and general principles of examina tions, 2 The nervous system, 3 Cardio vascular system; 4 Respiratory system, 5 Digestive system, 6 Urinary system, 7 Blood and blood forning organs, 8 Joints, 9 Ductless glands, 10 Skin and appendages, 11 Pyrexia

The text is well illustrated

Every effort has been made in the presentation to work from the patient and his complaint to the disease from which he suffers. The writers try to outline the mental processes which take place when the observer is faced with the patient.

PRINCIPLES OF CHEMISTRY An Introductory Textbook of Inorganic, Organic and Physiological Chemistry for Nurses and Students of Home Economics and Applied Chemistry with Laboratory Experiments By Joseph H Roe, Ph D Second Edition, 12mo of 427 pages, illustrated. St Louis, The C V Mosby Company, 1929 Cloth, \$250

This, the second edition of a well known text, has been thoroughly revised to bring it in line with the newer applied chemical procedures used in modern hospitals. For this reason and also because of the greater time now devoted in nurses' courses to the subject of chemistry, the author has added several chapters on the chemistry of the excretions and secretions. The subjects of the various chapters are well presented and follow one another in a logical sequence. It is an admirable text for nurses.

A. G.

COMMON INFECTIONS OF THE FEMALE URETHRA AND CERVIX BY FRANK KIDD MA, MCh, and A MALCOLM SIMPSON, BA., MB, DPH Octavo of 197
pages, illustrated London and New York Oxford
University Press, 1929 (Oxford Medical Publications)

Myths die hard and it is as true in medicine as in other branches in life.

If for no other reason this book is most valuable it proves that infection in the urethra, Skene's tubules, Bartholiman glands, etc., or in combination, is not due of necessity to Gonorrhea

The subject matter is listed under various sepirate chapters, each devoted to a special field, such as, Diagnosis and Treatment of Urethritis, Diagnosis and Treatment of Cervicitis, Gonoricea in Female Children, Gonococcal Arthritis in Women, etc. In fact, each point of infection and its complications is dealt with separately

Referring to a specific quotation of the author's thesis, we find 'It has been widely held that all inflammation of Bartholin's Glands are due to the gonococcus, and that an enlargement of Bartholin's Glands is evidence of impure connection. This is a gross fallacy and one that should be removed from the tv-tbooks' (p. 40)

This quotation is reviewed as it is so common to find

women falsely accused on a Bartholinitis

All the author's conclusions are checked and rechecked by the laboratory, and besides, a keen chinical acumen is shown throughout. One may differ in regard to the tratment outhined, but cannot challenge the results until the same circful laboratory checkup has been followed out. It is on this point that most teachers have failed

1061

This book is well worth review by every doctor and student, easy to read and less than two hundred pages

The only criticism is that the illustrations are possibly too few, and these few of not the quality that this book deserves

G W PHELAN

DISEASES OF THE THYROID GLAND BY ARTHUR E HERTZ-LER, M.D. Second Edition Octavo of 286 pages, illustrated St Louis, The C V Mosby Company, 1929 Cloth, \$7 50

In the second edition of his book on Diseases of the Thivoid Gland, 'Hertzler has given the surgical profession a very interesting personal narrative of his experiences in thyroid surgery. He has attempted to correlate the various phases of gottre on the theory that they represent different stages of the same disease. He bases this concept on the fact that he has seen the same individual pass through the whole gainut of changes, starting with a colloid gottre and terminating with a classic picture of Graves Disease. He emphasizes the fact that the pathology of the gottre is so frequently of a mixed character. He discusses the pathology of disease of the thyroid in considerable detail devoting over one fourth of the book to this phase of the subject. There is nothing new brought out under the heading of treatment. In his operative technique he prefers to divide and follow the deep fascia of the neck, thereby obtaining easier retraction of the ribbon muscles. The book is written in a terse manner, reads very easily and should be included in the library of anyone interested in diseases of the thyroid gland.

THE BLOOD PICTURE AND ITS CLINICAL SIGNIFICANCE (INCLUDING TROPICAL DISEASES) A Guidebook on the Microscopy of Blood By Professor Dr Victor Schilling Iranslated and edited by R B H Gradwoill, M D Seventh and Eighth Revised Edition Octavo of 408 pages illustrated St Louis, The C. V. Mosby Company, 1929 Cloth, \$10.00

This monograph of 418 pages and 5 plates covers a subject which is manifestly difficult to handle in view of the chaotic condition in which hematology finds itself. The book is divided into four parts, dealing with technique, theory, morphology and division of the blood picture, fundamental principles for clinical use for the blood picture, selected examples for practical use for hemograms. The plates are excellent, the literature is not thorough. The disease index is especially commendable. This work may be viewed from two standpoints. In the general practitioner and surgeon, 2. The hematologist. In neither of these cases does the book clarify matters. To the general practitioner and surgeon the material is presented in a confusing manner. To the hematologist nothing new is brought out with the exception of the 'Gutta diaphot' which at the present time must be regarded only is a fad. The subjects are treated in a lather sketchy manner and appear to have been prepared in haste, the thought is jerky. This is in all probability due to difficulties inherent in all translations.

There are too many maccuracies and omissions. One is painfully aware of the fact that this book is written by a German because of the great disregard of tings Figlish and American. Such names as Osler and Addison are omitted from the discussion from entities as Policythenna Vera (Vaquez) and Pernicious Anemia (Biermer).

It must be stated that after the thorough perusal of the book one would find little gems of thought which will reply the interested doctor, but otherwise the work is unwidth and too encyclopedic.

MAURICE MIRRISON

# OUR NEIGHBORS

## HOUSE OF DELEGATES IN ILLINOIS

The House of Delegates of the Illinois State Medical Society met on May 20, 1930, at Joliet, with the President, Dr. F. O. Fredrickson, presiding at the end of his second year of office. The State Society is in a prosperous condition with 7,485 members on April thirtieth. Its journal is one of the most representative of the medical profession that comes to our Editorial desk—evidence of which assertion is the fact that the Department of "Our Neighbors," which quotes only the actual doings of the medical societies of other states, quoted the Illinois Journal 14 times in 1929, a record exceeded by the number of those quoted from Wisconsin with 15 quotations, and equalled by Texas only.

The proceedings of the House of Delegates, including the reports of the officers and committees, fill 24 pages of the Jully issue of the *Illinois Medical Journal*.

Medical Students' Advisory Committee: The report of the president contained the following account of his efforts to reach the medical students and internes:

"Your President has had the opportunity and privilege of organizing in the Chicago and Illinois State Medical Societies, a medical students' advisory committee to promote and arrange lectures for medical students and internes on medical organization, economics, legislation and ethics. These lectures are to be given under the auspices of the Chicago and Illinois State Medical Societies. Your President was appointed chairman of a central committee with the deans of the medical schools as members. Visits were made to the fifteen branches of the Chicago Medical Society and local committees organized for arranging lectures to internes in the hospitals located in their districts. The work of the central and sub-committees is going on with increasing enthusiasm and it is hoped that the plan may extend to other cities in Illinois. This, your President thinks, should add many loyal workers for organized medicine in the future."

This subject is also considered by the Legislative Committee, which reported as follows:

"Another item of interest which may be properly contained in this report is the receipt of a letter from one of the largest Medical Schools in Illinois inviting a member of the Legislative Committee to address the student body regarding the future responsibilities in reference to legislative activities. He calls attention to the fact that 90 per cent of this student body will practice in Illi-

nois. The writer of the letter calls attention tethe fact that these students are in the formative state of mind and are receptive to many idea communicated to them. He further states that the Medical Students should, in his opinion, have an early contact with the leaders in their State Medical Society. For, as he puts it, they will be our future leaders and very pointedly conclude his letter with the following statement in reference to those students:

"They should begin early to realize that the cannot be rabidly individualistic, but must develo an interest and must be impressed with the ide that health and medical legislation is thei business."

District Councilors: The ten District Councilor make interesting reports, for they take thei duties seriously and actually see the county societies in operation. Dr. Weld, of the First Distric reported:

"In some counties the custom of having weekl meetings has been established. These meeting take the form of a service luncheon where the current literature is discussed, worthwhile paper by different members are read, and civic an community problems are discussed. Best of a we 'rub elbows,' get to know each other and develop a friendship toward our co-worker.

"Outstanding advance has been made in som of the larger centers of this district through th establishment of weekly pathological conference. Here medical men not only hear the history of the case and the diagnosis, but they see the grost pathological specimen, hear the pathological diagnosis and see the microscopical sections. These conferences provoke discussion as to diagnosis and treatment which in themselves are mentall stimulating."

Dr. Perisho, of the second district, wrote:

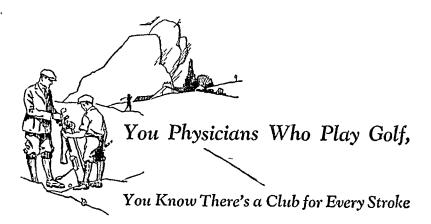

"I find evening meetings with a 6:00 P.N dinner followed by a program to be more successful than afternoon meetings,

"Most of the counties have made use of th scientific program committee in securing speaker for their programs, as well as the educations committee for their public meetings.

"I have encouraged the county organization of the women's auxiliary but as yet I have not me with much of any interest or success."

Dr. Coleman, of the Fourth District, met wit difficulty as follows:

(Continued on page 1064-adn rin)

Dextri-Maltose No. 1 (with 2% soduum chloride), for normal babies. Dextri-Maltose No. 2 (plain, salt free), for salt modifications by the physician. Dextri-Maltose No. 3 (with 3% potassium bicarbonate), for constipated babies. "Dextri-Maltose With Vitamin B" is now available for its appetite-and-growth-stimulating properties. Samples on request.

LMOST any player can swing around the course with a single club, dubbing drives, lifting fairway sods and bringing home a century mark or more for the final score. But the finished golfer needs a club for every shot—a studied judgment of approach or putt before the club is selected.

Similarly in artificial infant feeding. For the normal infant, you prefer cow's milk dilutions. For the athreptic or vomiting baby, you choose lactic acid milk. When there is diarrhea or marasmus, you decide upon protein milk. In certain other situations, your judgment is evaporated milk.

Dextri-Maltose is the carbohydrate of your choice for balancing all of the above "strokes" or formulae and aprly may be compared with the nice balance offered the experienced player, by matched clubs.

To each type of formula (be it fresh cow's milk, lactic acid milk, protein milk, evaporated or powdered milk), Dextri-Maltose figuratively and literally supplies

the nicely matched balance that gets results.

-MEAD JOHNSON & COMPANY, EVANSVILLE, IND., U.S.A.

in a most satisfactory way

Designed for relief of scrotal hernia—this garment performs its work better than any belt or truss on the market.

It hugs the body closely, following the groin line. Beneath—a fitted, resilient pad protects the ruptured part. Perineal straps fitting close to the side of the leg hold the pad firmly. No slipping from place. No irritation. The CAMP PATENTED ADJUSTMENT, lacing at back, pulling from lower front, governs tightness and pressure.

A support affording decided comfort to the patient. In different body heights, all sizes. Sold at the better drug and surgical houses.

## Digitalis in its Completeness

Physiologically tested leaves made into physiologically tested pills.

Pil. Digitalis (Davies, Rose) insure dependability in digitalis administration. Convenient in size—0.1 gram (1½ grains), being the average daily maintenance dose.

Sample and literature upon request.

DAVIES, ROSE & CO., Ltd. Pharmaceutical Manufacturers, Boston, Mass. (Continued from page 1062)

"The only disturbing element has occurred in one county, where a factional fight of many years' standing has culminated in a very distressing altercation over the question of hospital standard-The altercation has received so much publicity that the entire profession seems to have lost caste with the public and all concerned have suffered, even to the hospital, which is an innocent victim. On two occasions, the Councilor, in company once with a committee from the council, attended meetings and essayed the role of peacemaker. It is to be feared that the result will be about the same as when any well-intentioned peacemaker attempts to help settle a family quarrel; no settlement is made and the peacemaker wins the enmity of both sides. The committee from the council, suggested that the various factions try to compromise their difficulties, and it is felt that as the trouble is of local origin, it must be settled by the local men involved. With this exception, the Fourth District continues to radiate peace and harmony, and good professional feeling seems to prevail throughout."

Anti-Vivisection: The Legislative Committee made the following report on anti-vivisection:

"The Anti-Vivisectionists were a new group who sought legislative favor. They employed a very able attorney and their campaign was adequately financed, and they had a very imposing lobby of cultured and beautiful women. Without some study a physician does not realize the farreaching disastrous results that could occur if this group were successful in passing an Anti-Vivisection Bill. The disadvantage of using dogs and lower animals for experimental purposes and claims of the brutal treatment of dogs were exploded when a committee from the State Senate visited Northwestern Medical School and made a personal investigation of the kennels and the treatment that the dogs received. Although the bill was not reported out of committee last year, we are advised that a more persistent effort will be made at the coming session of the legislature in an effort to pass a similar measure."

Sanatologists: The sanatologists' group is growing in Illinois as is seen by the following report:

"The Sanatologists were unusually active with their insistent demand for recognition. To read their claims should be sufficient for any well-thinking person to refuse to support a bill of that type; however, they received nearly half of the constitutional majority of the votes in the House, which conclusively demonstrates that all matters pertaining to the healing art must be continually supervised by medical men so that legislators may have the advantage of professional advice when considering medical matters."

Committee on Publication

(Continued from page 1064-xiv)

Old Age Pension: Illinois, unlike New York, has opposed old-age pensions:

"Several old age pension bills went into the discard. Old age pensions are not far removed from a universal compulsory health insurance law, and both are closely related to State medicine."

Medico-Legal Committee: The Medico-Legal Committee reported:

"For the year ending May 1, 1930, there were eighty suits pending as compared with eighty-six on May 1, 1929. The total number of claims to May 1, 1929, were thirty-nine, as compared with thirty-three for May 1, 1930. This is a decrease in the number of suits for the last two years. There have been three expensive suits defended, two of them sponge cases and one a Lane plate case. The sponge cases are our serious cases. The law is not favorable to the doctor in these cases. A sponge found is evidence that it was left by the surgeon, and the burden is then placed on him to prove his innocence, and it cannot be shifted to the Hospital or Assistant without great difficulty."

Scientific Service Committee: The Scientific Service Committee assists County Societies in arranging their programs, and sends speakers to them. In fact it is doing post-graduate work similar to that of the New York State Society. The report says:

"During the past twelve months this sub-committee has continued to function as a speakers' bureau. A detailed report shows ninety-eight speakers have appeared in forty-two different counties, indicating nearly half the counties in the state are making some use of this committee. Two clinics for crippled children were arranged and conducted by Warren and Perry County Medical Societies.

"An increased percentage of the papers given during the last twelve months have been on obstetrics and pediatrics. These programs seem to be of interest to practically all physicians. Illinois is doing as much in the field of post-graduate work in obstetrics and pediatrics as any other state in the union.

"With the introduction of the Jones-Cooper Bill behind which is a renewed effort to continue in a more pernicious form the activities of the Sheppard-Towner Act, it becomes increasingly important that our Society take definite steps toward improving the maternal and infant mortality rate in this state."

Educational Committee: The Illinois State Medical Society does outstanding work in popular medical education. This activity is in charge of the Educational Committee whose report, compressed to the limit, fills three pages. This Com-

### HAY FEVER

#### An Advertising Statement

HAY FEVER, as it occurs throughout the United States, is actually perennial rather than seasonal, in character.

Because in the Southwest—Bermuda grass, for instance, continues to flower until December when the mountain cedar, of many victims, starts to shed its pollen in Northern Texas and so continues into February. At that time, elsewhere in the South, the oak, birch, pecan, hickory and other trees begin to contribute their respective quotas of atmospheric pollen.

But, nevertheless, hay fever in the Northern States at least, is in fact seasonal in character and of three types, viz.:

TREE HAY FEVER—March, April and May GRASS HAY FEVER—May, June and July WEED HAY FEVER — August to Frost

And this last, the late summer type, is usually the most serious and difficult to treat as partly due to the greater diversity of late summer pollens as regionally dispersed.

With the above before us, as to the several types of regional and seasonal hay fever, it is important to emphasize that Arlco-Pollen Extracts for diagnosis and treatment cover adequately and accurately all sections and all seasons—North, East, South and West.

FOR DIAGNOSIS each pollen is supplied in individual extract only. FOR TREATMENT each pollen is supplied in individual treatment set.

ALSO FOR TREATMENT we have a few logically conceived and scientifically justified mixtures of biologically related and simultaneously pollinating plants. Hence, in these mixtures the several pollens are mutually helpful in building the desired group tolerance.

THE ARLINGTON CHEMICAL COMPANY YONKERS, N. Y.

(Continued from page 1066-adv. xvi) mittee is in close touch with the Parent-Teachers Associations, the Federation of Women's Clubs, the Public Schools, the Radio, and the Daily Press. Descriptions of the work in Illinois appeared in the New York State Journal of MEDICINE during the year 1929, as follows:

> January 1, page 60. August 15, page 1036. December 1, page 1496. December 15, page 1556.

The report to the House of Delegates amplifies the descriptions which have already been quoted in the New York State Journal of Medicine.

#### CLINICS IN CALIFORNIA

The July issue of California and Western Medicine contains a seven-page report of the Committee on Clinics of the California Medical Association. The report says:

"The types of Clinics in the State of California are:

"(1) Charitable clinics, 80 per cent. "(2) Private clinics, 9 per cent.

"(3) Commercial clinics, 11 per cent.

"Note: This survey does not include those clinics and out-patient departments coming under the jurisdiction of the Compensation Insurance

Some California Clinic Statistics

"A. (1) Charitable clinics in the State of California, 175.

"(2) Total visits made to these departments

for one year (175 clinics), 1,195,390.

"(3) Total number of free patients seen, 646,-

"(4) Total number of new patients seen for these clinics, 235,470.

"(5) Total amount of money collected from

patients, \$290,679.25.

"(6) Total cost of operation of these clinics. \$2,132,555.01. Average cost per visit is \$1.78."

The report lists 20 cities in which charity clinics are run, and 14 counties have health department clinics. Regarding private clinics, the report

"Private clinics in the State of California are

as follows:

"(Cost on these clinics are not available be-(Continued on page 1070 -adv. xx)

## TRADE PYRIDIUM MARK

Phenylazo-alpha-alpha-diamino-pyridine hydrochloride (Manufactured by The Pyridium Corp.)

## For the treatment of urinary infections

May be administered orally or applied locally.

Non-toxic and non-irritative in therapeutic doses.

Marked tissue penetrative power.

Rapidly eliminated through the urinary tract.

## make Nourishing Foods

taste better with this

THIS is one of the advertisements of The Sugar Institute, appearing in newspapers throughout the country. In order to keep the statements in accord with modern medical practice, they have been submitted to and approved by some of the leading authorities in the field of human nutrition in the United States.

## New Seasoning

THE OLD PROVERS SAIS, "Hunger is a good sauce." But what is to be done when there is no appetite or hunger for the foods we should eat?

There is no seasoning more unusual than a combination of sugar and salt in giving familiar foods a new and appetizing flavor. Just taste a pinch of salt and a dash of sugar mixed together and you'll realize what a full-bodied goodness they make.

Then, try such a mixture of salt and sugar in cooking vegetables. In peas, tomatoes, carrots, spinach and cabbage, a level teaspoonful is enough, but suit your taste. Put it in soups, stews, or cereals as they cook. You'll be surprised to learn that the sugar not only blends deliciously with the flavor of the dish, but emphasizes it.

The most popular mixture to use and keep on hand is equal parts of sugar and salt. You may prefer one part sugar with two parts salt.

Doctors and dicticians recommend the use of sugar as a flavor. Not only does the sugar promote the necessary flow of gastric junces but it is quickly converted into energy. The Sugar Institute, 129 Front Street, New York.

For nearly twenty years, "Hindle" Electrocardiographs have been the accepted standard of prominent American hospitals and notable Cardiologists. Over 750 are now in everyday service. Models are available for every requirement of the Hospital, Clinic, Research Laboratory or Private Office.

Send for Literature

## CAMBRIDGE INSTRUMENT CO INS

3512 Grand Central Terminal New York (Continued from page 1071-adv. xxi)

operation expenses are entered against the paying portion of the hospital so as to reduce the cost for the care of the members of the society wherever possible. In other words, the sum \$22.61 per capita per annum would be considerably larger if the hospital were operated for members only.

"The outstanding fact of value to you is that this institution, if it charged \$22.61 per person per annum for medical care without medical or surgical fees, would soon be bankrupt were it not for the fact that it has a return from investments from its endowments and gleans a profit from outside non-member pay patients."

The Committee reported its studies of sickness in over three thousand families, as follows:

"I am able to present a record of the cost of sickness to 3,281 American families over a period of six months from the first of January, 1929, to the first of July, 1929.

"These families are all above the poverty line, but cannot be considered in any way as representing financially the average California family. These families range, in numbers per family, from one to nine and over, and the expenditure being for a period of six months will have to be multiplied by two to secure the estimated annual expenditure.

"Of the 3,281 families studied there were:
"198 families that made no expenditure for

"1,113 families spent less than \$25.

"654 families spent from \$25 to \$49.

"655 families spent from \$50 to \$99. "397 families spent from \$100 to \$199.

"135 families spent from \$200 to \$299.

"55 families spent from \$300 to \$399.

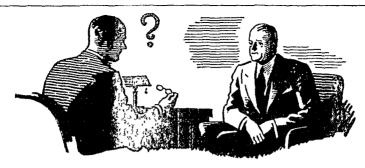

"36 families spent from \$400 to \$499.

"38 families spent \$500 or more.

"Remember that these are expenditures for six months only. Of these families there were twenty with only one in the family and the average expenditure for sickness for six months was \$72, which would be \$144 per year per person."

The following table shows the expenses in greater detail:

Number of	Individuals N	Sedical Expenses
families	in Each Family	in 6 Months
20	1	72
128	2	82

## The Answer to the "first Question"

BEFORE prescribing for any ailment the first question the physician asks the patient concerns the function of the bowels. A very necessary question, to be sure.

Then he must ask himself what corrective to prescribe to suit the condition, without interfering with the treatment.

Agarol is a safe answer to the question that the physician, of needs, must ask himself many times every day.

Agarol, the original mineral oil and agaragar emulsion with phenolphthalein, is free from any artificial flavoring, sugar, alkali or alcohol. It is safe in diabetes, in gastric diseases, for children as well as adults. No excess of mineral oil to interfere with digestion or to cause leakage.

In addition, gentle stimulation of peristalsis, makes the result certain and the reestablishment of regular habits possible. One tablespoonful at bedtime

—is the dose

Final decision on the true worth of Agarol rests with the physician. We will gladly send a twin package, with literature, for trial.

#### STATE SOCIETY LABORA-TORY FOR RHODE ISLAND

The annual address by Dr. F. T. Fulton, President of the Rhode Island Medical Society, given on June 5, printed in the Rhode Island Medical Journal, discusses periodic health examinations and suggests that a laboratory be established for the use of physicians making the examinations. The president says:---

"I would like to suggest here something which so far as I know has not yet been tried, and that is the establishment of a laboratory which should be the property of, and financed by the Society, a laboratory with a director of high attainments, a laboratory which would furnish all of the technical examinations which might be required, such as all varieties of blood examinations, metabolism tests, electrocardiograms, x-rays, etc. Such a laboratory should be able to furnish to the members of the Society these examinations at considerable less cost, because of the diminished overhead, than can be furnished by numerous private laboratories.

"The question may be asked as to how such a laboratory could be financed. It might be done in various ways. The dues of our Society at the present are ten dollars a year, which includes the pay for a dinner. There are four hundred and fifty members in the Society. If each member would pay into the Society in the course of a year an amount equivalent to the average dues of the University Club or one of the golf clubs to which a good many members belong, it would amount to between twenty-five and thirty thousand dollars, possibly more. Such a sum would be sufficient to equip the finest sort of a laboratory and make a good start in paying for its maintenance for the first

#### DIET QUESTIONS have GELATINE ANSWERS

## APPETIZING VARIETY IN THE DIABETIC DIET

For Example...

JELLIED CHICKEN IN CREAM (Siz Servings)

I tablespoonful Knox	Grams	Prot.	Fat	Carb.	Cal.
Sparkling Gelatine	7	6		•••	••••
or water 13f cups boiling chicken	••••	****			***
broth, fat free	****	٠.	٠.	****	
34 teaspoon salt		٠.	• • • •		
Pinch pepper	****		•••	••	••
1 cup cooked chicken,	125	24	20		
3f cup cream, whipped.	55_	1	_22	15	
One se	Total	٤١ 6	44	15	5.3 £8

Soak gelatine in cold liquid for five minutes and dissolve in hot broth. Season with salt and pepper and chill until nearly set, Foldin chicken and whipped cream. Tarn into wet mode and chill until firm. Serve on lettuce or garnish with parsley and stifp of plinesto.

KNOX
is the real
GELATINE

Every physician knows the difficulty of diet control in diabetes.

The solution is quite simple.

With Knox Sparkling Gelatine, the taste dissatisfaction with the monotony of the diabetic diet may be almost entirely dispelled, without disturbing the purpose or the balance of the diet in the slightest degree.

Where small quantities of vegetables, meat or fish are necessary, satisfying bulk may be supplied with Knox Gelatine, which combines perfectly with these essential foods, making them more attractive to the eye and continuously delightful to the taste.

With Knox Gelatine, a different dish may be served every day from the basic foods of the diabetic diet.

In prescribing gelatine it is essential to specify KNOX, because of its established purity and absolute freedom from sugar, and also to end any confusion that may exist in the public mind as to what is meant by "gelatine".

If, for instance, a ready-sweetened, flavored and colored brand of gelatine is used, the patient gets about 87% sugar, which is, of itself, sufficient to defeat the purpose of the diabetic diet.

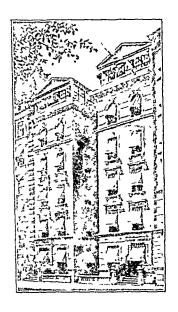

Knox Gelatine is just pure gelatine, containing no sweetening, no flavoring, no coloring, no acid.

We would like to send every physician a treatise on "Diet in the Treatment of Diabetes" by Lulu G. Graves, Honorary President of the American Dietetic Association. This treatise presents many new ideas and recipes in the preparation of beneficial diabetic diets. It is of such character that it may be placed in the hands of any patient with the assurance that it will act as a safe diet control, and at the same time make the patient as happy with his food as though he were not on a diet. This treatise will be sent in any quantity, to supply the diabetic patients of any physician who will mail this coupon.

KNOX GELATINE LABORATORIES
432 Knox Avenue, Johnstown, N. Y.
Please send me, without obligation or expense, the booklets which I have marked. Also register my name for future reports on clinical gelatine tests as they are issued.

### A New Way of Using the Salicylates

Recent investigations favor the concomitant use of alkalis in salicylate administration — the combined form of treatment enhances the therapeutic value of the salicylates by combating the associated acidosis.

More recently it has been demonstrated that the most convenient and effective method of insuring alkalization is by the use of a balanced alkali formula in preference to single salts.

And hence the reason for the introduction of

ALYCIN
presents 20 grains
Merrell's Natural Sodium
Salicylate, together with 40 grains
of alkali base.

Because Merrell's Natural Salicylates are free from the usual gastric symptoms associated with the synthetic salts, the dose of ALYCIN can be pushed so as to obtain the full salicylic effect within the first 48 hours. ALYCIN is supplied in convenient form for routine use.

Write for sample and literature at once and start this more effective method of salicylate medication.

#### COPPER IONIZATION IN THE TREATMENT OF CERVICITIS. By DAVID W. TOVEY, M.D., F.A.C.S., NEW YORK, N. Y.

A T the last meeting of the American Gynecological Society, Lucas E. Burchi of Nashville, Tennessee, read a paper, by invitation, in which he advocated a method he has devised. of dilating and splitting the cervix to the internal os, to allow cauterization of the exposed endocervix, to cure cervicitis.

Burch said he had devised this radical procedure as linear cauterization, diathermy and

tropical applications were ineffective.

John A. McGlum of Philadelphia advocated the use of the cautery but thought splitting the

cervix to apply it as too radical.

In France, the Fillos caustic pencil, potassium and sodium hydroxide, is extensively used. The serosanguineous discharge from its use is very caustic and to be feared, says L. Pouliot.2

Pollak and Curtis use radium.3

That so radical procedure as bisecting the cervix to cauterize it was advocated at the last meeting of the foremost gynecologists of the country, shows the difficulty of curing cervicitis.

I believe the caustic pencil, cautery, radium and high frequency current will cure these cases, but except in the hands of the expert gynecologist, are dangerous.

L. Fulkerson reports: "Late sloughing, late and alarming hemorrhage after cauterization by other operators."4

Brunner reported: "A case of complete atresia of the cervical canal due to faulty cauterization and its treatments."5

The author has seen premature menopause following the use of radium.

The method advocated has not these dangers. The sooner it is realized that there is no parallel between cauterization and ionization, the

better it will be for an appreciation of the therapeutics of cervicitis.

Copper ionization causes chemical infiltration, them. These forces are electrical repulsion and

coagulation and dehydration. Copper salts are carried by the forces in the tissues, sterilizing lymphatic currents. The effect of the copper extends deep into the tissues and lymph channels. (See illustrations.)

Dr. A. J. Quimby, Roentgenologist of the Polyclinic Hospital, used copper ionization years ago when he had a combined practice of x-ray and electrotherapsutics and before the significance of the pathology of cervical infection was understood. He urged me to use this method. So, when Dr. Richard Kovacs in charge of Physical Therapy at the Polyclinic Hospital, asked me to treat cases of cervicitis in his department, I welcomed the chance. The results were so good I applied the method in private practice.

The method is rational office procedure and is not advocated as a substitute for the Sturmdorf or Schroeder operation. Where these operations are indicated, it will sterilize and shrink the tissues and put them in a condition that makes the operation safer and less extensive. After the operation, it will sterilize any glands or infection in the remaining tissue. The results in thirty cases were a cure of the cervicitis, making operation unnecessary. It is a safe substitution for the cautery, but I do not say, as does Fulkerson of the cautery, "Like Kelly, I no longer operate for chronic cervicitis." L. M. Fulkerson. Cynecology, 1929.

To show the erroneous ideas distributed about copper ionization. In a book published by a commercial house for the instruction of those buying their electrical generator, under the heading of "Cervicitis and Endometritis," they write: "The treatment for both cervicitis and endometritis is the use of the positive pole of the galvanic current with a copper or zinc intrauterine electrode, to drive into the mucus membrane the oxychloride of copper or zinc."

The results obtained are due to the effect upon the cervix and not on the endometrium.

In the same book under "Cervical Catarrh": "Introduce the copper electrode up to the internal os, employ a current of 30 to 40 milliamperes. In a few minutes or a little longer, the instrument will be found to be tightly stuck, but by traction, it can be withdrawn. Some bleeding may follow. The cervical canal will be denuded clear to the Nabothian glands. We have, in fact, curetted the cervical canal and have deposited the copper salt throughout the cervical region."

It is useless to curette the cervix as the glands extend deep into the tissues and cannot be re-

moved with any curetting method.

To do as is advised would cause great pain, traumatism and destruction of cervical tissue. The high amperage used would coagulate the tissue suddenly and prevent the penetration of the copper. Higher than 25 milliamperes should not be used, usually 10 or 12. The current should be applied for at *least* fifteen to twenty minutes.

Ionization is the introduction of the ions into the tissues by means of the galvanic current.

Ions travel at a comparatively slow rate of speed. The amount of drug driven into the tissues is in direct proportion to the amount of current, the length of time the current is flowing and the size of the electrode used. But a longer treatment with a relatively small amperage will drive ions deeper into the tissues than a short

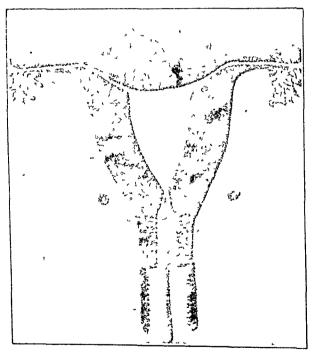

FIGURE 1

Illustration showing lymphatics of the interus with electrode in the cervix driving copper into the tissues and lymph channels in the direction of the lymphatic drainage and electric current. The light area between the electrode and cervix represents the margin of coagulation. Two circular areas at outer side of interus represent the ureters.

treatment and high amperage. The larger the surface of the electrode, the greater the amount of current used.

A. Judson Quimby estimates that with the large cervical electrode, 10 milliamperes for

twenty minutes, 200 milliampere minutes, copper can be driven into the tissues of the cervix for about eight millimeters.<sup>7</sup>

The human body is a sac containing fluids which hold various salts in solution, the chief of which is sodium chloride. The galvanic current, owing to its chemical action, splits these salts into their various constituents (ionization), the metallic portion being attracted to the negative pole and the acid portion to the positive pole.

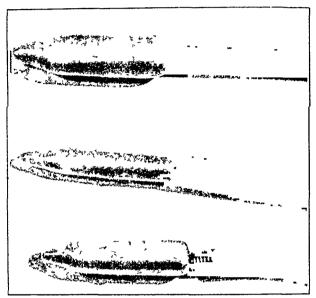

FIGURE 2

The electrodes are one and a quarter inches or four centimeters long, 16 to 28 French in diameter. The small rounded end enters but will not pass the internal os, being prevented by the rounded shoulder.

Knowing that the positive pole attracts acid radicals and repels basic elements as metals, it will, therefore, be clear that if we wish to introduce a metal into the tissues, we must use the positive pole. If we wish to drive acid forming elements into the tissues, we use the negative pole.

The positive pole is the acid pole and is a vaso constructor. It has the following effects:

- 1. Contracts and hardens tissues, dries discharges, coagulates albuminoids.
- 2. Has a sedative effect.
- 3. Decreases inflammation.
- 4. Dries or dehydrates tissue.
- 5. Copper, zinc and other metals are applied at this pole.
- 6. It is germicidal.

The negative pole is alkaline, caustic and has the following effects:

- 1. It is a vasodilator and, therefore, causes congestion.
- 2. Relaxes, softens and liquifies tissue.
- 3. Liquifies secretions.
- 4. Increases moisture.

This pole is used to introduce acid radicals into the tissues in ionic medicatin as the halogens. A mild sensation of burning is felt at the negative pole because of its caustic properties.

It is very important with the galvanic current to be able to be quite certain which is the positive and which is the negative pole, owing to the fact that each pole produces a widely different effect, both chemically and physiologically.

The simplest test for "polarity" is as follows: Place the metal ends of the cords in water. Have them close to each other but not touching. Turn on the current slowly. It will be noticed that one of the electrodes is covered and surrounded by tiny bubbles of gas, this is hydrogen which is freed at the negative pole.

Apparatus used: 1. A galvanic unit gauged in milliamperes. 2. Asbestos pad. 3. My intra.-

cervical electrodes.

There are no intracvervical electrodes on the market, only the long intrauterine electrodes. At first, I used the shortest and thickest copper electrodes I could find, about two and a half inches long, the Goulet intrauterine electrode. Some of the electrodes on the market are three inches long. Unless one is very careful, these thin electrodes pass through the internal os into the cavity of the uterus.

The effect of the electrode on the uterine tissues causes a delay of the menses for from tendays to two weeks, and uterine colic.

The cervical electrodes shown in the illustration were designed by me in four sizes, 16 to 28 French in diameter, four centimeters long. The small rounded upper end enters but does not go through the internal os. The bulbous upper part will not enter the uterine cavity unless undue pressure is made.

I have had no treatment followed by uterine colic or delay of the menses since I have used the intracervical electrodes.

Technique: The wet asbestos pad, connected to the negative pole, is placed under the buttocks. The electrode with the plus pole is inserted into the cervix and dilates it.

Should the external os be so small that it will not admit the smallest electrode, the tip of the electrode is inserted into the external os and the current changed to negative. This will cause softening and relaxation of the cervical tissues so the electrode can be passed to the internal os. The current is then changed to positive and the reostat set at 10 to 12 milliamperes for twenty minutes. Cotton is packed about the electrode to support it and to prevent contact with the speculum. At the end of the treatment, the electrode and os will be seen to be surrounded by copper crystals which have been deposited upon and driven into the cervical tissues. It will be found impossible to withdraw it without

trauma. It has become adherent from coagulation, contraction and dehydration of tissues and ionization of copper. The current is now reversed so the electrode is connected to the negative pole. In one or two minutes, relaxation and softening of the cervical tissue occurs. The copper crystals about the external os are seen to become moistened by secretion. When traction is made on the electrode, it will be felt to loosen and can be withdrawn.

Turn the current off slowly before changing from the positive to the negative pole If this is not done, the patient will experience a dis-

agreeable shock.

The results of copper ionization are a lessening of the discharge. In a week or ten days it has disappeared, the cervix shrinks and after three or four treatments, it appears normal. The infection, erosion, Nabothian cysts and discharge have disappeared.

Large infected cervices that in the past re-

quired amputation shrink to normal.

Treatment should not be repeated oftener than ten days to two weeks. It takes this time for tissue changes and healing to take place. If given more frequently, the changes cannot be watched and there is danger of overcontraction and shrinking of the tissues of the cervix.

In England, zinc ionization is used in the ear with success. John McCoy and others have reported good results from its use in the ear in

this country.

I believe that copper which is the stronger antiseptic and better tolerated by the tissues, would be used in the ear were it not for its staining properties.

My electrodes are made of zinc as well as of

copper. 57 West 5th St.

## THE DIFFERENTIAL DIAGNOSIS OF THE GLYCOSURIAS\* By BYRON D. BOWEN, M.D., BUFFALO, N. Y.

BVIOUSLY if a patient has diabetes all haste should be made to treat it but if he has not the rigors of dietary restriction should not be imposed. Physicians, however, should consider every case of glycosuria diabetes until it is definitely proven otherwise. The object of this communication is to discuss the technic of this differential diagnosis.

In reading the literature one is impressed by the multiplicity of terms used in describing non-diabetic glycosuria. Thus we have: diabetes innocens or innocuous, benign glycosuria, prediabetes, potential diabetes, alimentary glycosuria, cyclic hyperglycemia with glycosuria, renal diabetes, orthoglycemic glycosuria and transitional glycosuria. It is important to know that aside from diabetes mellitus, low threshold types, normal or slightly subnormal threshold types, and combined types occur. The differentiation is usually roughly made by the use of the glucose tolerance test, or by the use of a standard meal, blood and urine specimens being taken before and after half-hourly or hourly intervals for two to four hours. If the threshold is to be determined more accurately, observations must be made at shorter intervals.

Renal diabetes or low threshold glycosuria is readily recognized by the use of the glucose tolerance test; the range of blood sugar is usually low—60 to 130 mg. and there is continuous glycosuria at all blood sugar levels. Some authentic cases have been reported in which the twenty-four hour sugar excretion had exceeded 100 Gm. and which was not entirely dependent upon the food intake. This phenomenon is probably caused by an increased permeability of the glomeruli, or by deficient absorption of glucose from the renal tubules.

The most frequently observed type of nondiabetic glycosuria is that known by the older writers as alimentary glycosuria. To this Holst has given the name glycosuria with cyclic hyperglycemia, indicating a blood sugar rise after the ingestion of food with glycosuria at or above the normal threshold. The fasting blood sugar is normal and usually there is no hyperglycemia at the end of two hours after a meal. He also distinguishes certain combinations of the two general types of renal and alimentary glycosuria. In one, glycosuria may be present at all blood sugar levels and yet hyperglycemia is as extreme as is seen in cyclic hyperglycemia; in another, the so-called transitional type, there is a threshold point that is lower than normal but not as low as is found in the true renal cases.

Considering early diabetes, there does not appear to be any universally adopted methods of diagnosis. The so-called diabetic symptoms are not present in early cases or in some of the moderately severe ones. Mild diabetes is frequently uncovered by routine examination and its treatment at that stage is important in the prevention of a more severe form and possibly in delaying premature arteriosclerosis. seems quite certain that many severe cases have had mild and symptomless diabetes over a long period of years. The practice has often been to treat every case of glycosuria as diabetes until it is proven otherwise; this procedure may differentiate renal from true diabetes if blood sugar tests are made, but it will not eliminate the alimentary type; in fact dietary restriction often makes the diagnosis impossible. Joslin states that persistence of glycosuria while the patient is on a liberal diet with the fasting blood sugar above 140 or above 160 mg. after a meal indicates diabetes. Williams and Humphrey used the glucose tolerance test in 1919 in a group of patients with diabetes and glycosuria and at that time they felt that the occurrence of a high blood sugar within a half hour after the glucose, together with the persistence of hyperglycemia for an hour or so and the increasing glycosuria, was indicative of the early stages of diabetes. In 1923 John concluded that if the blood sugar returns to normal at the end of two hours after the oral administration of 100 gms. of glucose, diabetes did not exist; if it was normal in three hours then the patient was a prediabetic and if it was normal only after four hours, the diagnosis of diabetes could be definitely established. In a later communication he states that the diagnosis of diabetes may be safely eliminated if there is no hyperglycemia exactly three hours after the ingestion of a heavy carbohydrate meal. Likewise, Fitz believes that diabetes is present if the blood sugar two hours after a heavy carbohydrate meal exceeds 150 mg. Wright applied a modified tolerance test to 179 patients who had shown glycosuria; 68 of these had a normal fasting blood sugar but showed hyperglycemia and glycosuria two hours after the meal. Because of the lack of unanimous opinion in the interpretation of the glucose tolerance test, Petty and Stoner recommended the determination of the respiratory quotient after glucose administration as being a more dependable test of the ability of the patient to utilize carbohydrate. They conclude that this method of differentiation is more dependable and by means of it true diabetes may be diagnosed earlier. They found a number of patients whose blood sugar rose above

<sup>\*</sup> Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y., June 4th, 1929.

180 mg. but returned to normal in less than three hours to have respiratory quotient curves that indicated diabetes.

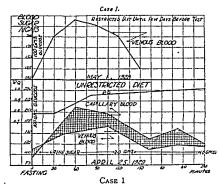

All observers agree that definite fasting hyperglycemia, in the absence of such conditions as hyperthyroidism, apoplexy, chronic nephritis with uremia, some diseases of the liver, and febrile diseases, indicates diabetes mellitus. On the other hand cases showing normal fasting blood sugar, alimentary hyperglycemia and glycosuria are not so readily put into their proper categories. In the report of Joslin and Lahey on diabetes and hyperthyroidism they considered all patients whose fasting blood sugar exceeded 150 mg. to have diabetes as well as hyperthyroidism.

Scandinavian physicians have studied this subject for a period of years but little attention has been paid to their conclusions in this country. After painstaking observations, all of them, including Hatlehol, Holst, Faber, Akerren and Malmros, arrive at the rather simple conclusion that the fasting blood sugar is the most important diagnostic criterion. stipulate emphatically, however, that all tests should be made during a period while the patient is taking a full and unrestricted diet. Under these circumstances if the fasting blood sugar is 110 or less, diabetes is highly improbable, if it is between 110 and 130 diabetes may be present and therefore the case should be placed under observation; and if it exceeds 130 the diagnosis is certain in the absence of the above mentioned conditions which may in themselves be accompanied by fasting hyper-glycemia. Holst has often found alimentary hyperglycemia to be a transitory phenomenon, and he does not consider the height of the alimentary rise specific for diabetes mellitus. He reports the case of a patient who had had glycosuria for 25 years and whose blood sugar rose to 276 mg. after the administration of 62 grams of glucose; on the other hand, other cases showed strong hyperglycemia 3 hours after glucose administration. Holst further studied 150 cases which had been rejected for life insurance because of glycosuria and in which he found diabetes mellitus in only about 30 per cent after an observation period lasting from 5 to 16 years. He states that he has never seen a case that has been definitely diagnosed benign glycosuria which later developed into true diabetes. Malmros in a recent monograph on this subject comes to the following conclusions: (1) If a patient shows normal fasting blood sugar without preceding dictary restriction, it argues against diabetes. (2) Mild cases of diabetes may have normal fasting blood sugar at least on some days in the beginning of the disease. (3) Patients having normal fasting blood sugar and alimentary hyperglycemia which falls slowly should

be put under observation. (4) The exclusion of diabetes is warranted only when normal fasting blood sugar is found over a period of weeks, even months. He has had one patient who was known to have had glycosuria for 41 years and whose fasting blood sugar was normal but rose to 240 mg. after glucose administration and returned to normal at the end of 2 hours.

During the past four years I have applied these diagnostic principles to border-line cases. The following are cases that have been under observation for some time:

Case 1. A man of 53 who in 1904 was told that he had diabetes. He suffered a "nervous breakdown" at that time because he was badly frightened. Later, both in England and in Germany, physicians diagnosed his case, "nervous diabetes." His weight was 120 lbs. He states that he had always enjoyed fair health but that sugar was usually found in his urine. He never observed a strict diet but he did avoid large quantities of starches and sweets. Overindulgence was followed by thirst, polyuria and nocturia. He would always be awakened at night when he ate a piece of pie for supper. Maximum weight, 170 lbs. in 1925; average weight, 145; height, 69 in. No family history of diabetes as far as he knows. Physical examination was essentially negative. Blood pressure, 105 systolic and 50 diastolic. Urinalysis, normal except for sugar. Blood cholesterol 120 mg. Wassermann reaction. negative. No definite impairment of gall bladder function by the cholecystographic method. The patient had been on an unrestricted diet

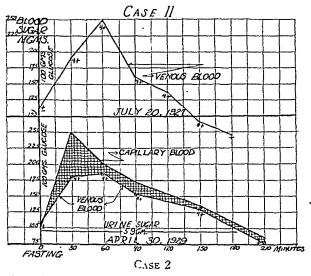

Normal fasting blood sugar; alimentary hyperglycenia with slow rise and fall and glycosuria, hyperglycenia at the end of two hours; normal difference between venous and capillary blood sugar curves, normal respiratory quotient curve, wilized 97 of the 100 gms. of glucose, threshold, probably about normal.

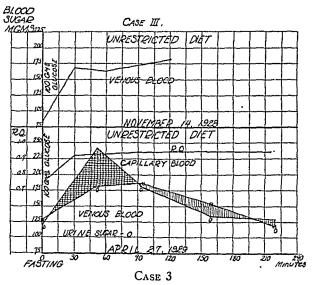

before all tests. Numerous fasting blood sugar values were always normal.

Case 2. A healthy man of 40 who was first seen in July, 1927, a few days after he had found sugar in his urine prior to an insurance examination. He had reduced his diet considerably but had failed to eliminate the glycosu-His digestion blood sugar was 133 mg. Other laboratory examinations and physical examination were negative. He was instructed to eat liberally of everything for several days before a glucose tolerance test was made. The results of this were indeterminate, so that he was placed on a diet of about 150 Gms. of carbohydrate and 2200 calories for nearly a year. The fasting blood sugar remained normal but glycosuria was usually present. He was then placed on a full diet again and six weeks later his fasting blood sugar was 80 mg. He had been on such a diet, avoiding large quantities of sweets, for nearly a year prior to the second tolerance test. He feels perfectly well except for slight pains in the legs; he has no symptoms of diabetes. Weight, 158 lbs.; height, 69 in.; blood cholesterol, 163 mg.

Normal fasting blood sugar; alimentary hyperglycemia, not as extreme in the second test; glycosuria at all blood sugar levels, slight at the fasting point; blood sugar not quite normal at the end of two hours; hypoglycemia at the end of three hours when symptoms of a mild insulin reaction were experienced; utilized about 94 of the 100 gms. of glucosc.

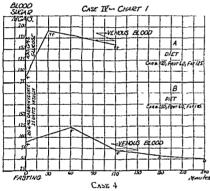

Case 3. An unmarried woman aged 20 who had been well up to two years ago, when irregular, gradually diminishing, and finally complete cessation of menstruation developed. She has had distressing bitemporal headaches for about a year; thirst, polyuria, and nocturia for more than a year; sometimes she drinks six quarts of water daily. Her weight has increased 50 lbs. in the past two years, during in size. Her features have changed in the past eighteen months so that her old friends do not recognize her; the features are coarse and her expression is rather dull. The visual fields were normal by gross tests. The jaw is large but not overshot. The hands and feet are very large and "pudgy" but the fingers are tapering. Her weight was 167 lbs, and the blood pressure was 115 systolic and 70 diastolic. was negative on many examinations except for the low specific gravity—1.002 to 1.005. The Wassermann reaction was +++. The fasting blood sugar was 85 and later 60 mg. while taking a full diet. The x-ray picture of the head showed a rather large sella turcica, and absent right frontal sinus and a small left. The glucose tolerance tests are shown in Chart 3. Blood cholesterol, 139 mg.

Typical diabetic curves except for the normal fasting blood sugar values in first test; normal difference be-tween capillary and venous blood sugar during the first 90 minutes; respiratory quotient curve probably within normal limits; all the glucose utilized; tremendous thirst during test; voided 1300 cc. of urine in 3.5 hours.

Case 4. A man aged 52 was first seen in April, 1924, when he entered the hospital because of "diabetes" and periodic attacks of pain in the upper abdomen which were relieved by alkali. He had never had any diabetic symptoms. He had been on a diabetic diet for about six months, and for the past few months, because the glycosuria did not disappear, he had been given increasing doses of insulin. Prior to admission he was receiving 68 units a day. He had had frequent insulin reactions and was once in coma so that glucose had to be administered. Physical examination was essentially negative; his weight was 157 lbs. His urine showed a trace of albumin but no casts. He was observed on high diabetic which time her hands and feet have increased diets but no insulin was given. His daily urine

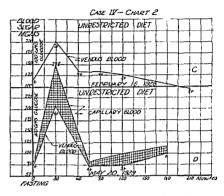

always showed a few grams of sugar but no ketones. His blood urea nitrogen on two occasions was about 30 mg. There was no fixation of the urine specific gravity, and but slight nocturnal polyuria. The stomach contents showed HC1 and no blood. The stool was negative for blood on several occasions. Wassermann reaction was negative. The diagnosis of renal diabetes was made and he was not seen again until February, 1928, when he was admitted to the surgical service for gastroenterostomy. He had had "ulcer symptoms" for about three months, but no diabetic symptoms. His urine contained a trace of albumin and sugar in all specimens and a few hyaline casts in several. He made an uneventful recovery. He was seen again in May, 1929, and was entirely free from symptoms. His urine was unaltered and his blood urea nitrogen was 26 mg.; blood cholesterol, 148 mg.

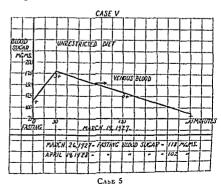

- A. Normal fasting blood sugar, moderate alimentary rise with hyperglycemia at end of two hours; low renal threshold.
- B. Normal fasting blood sugar; sugar in urine until blood sugar was brought below 75 mg. by insulin.
- C. Normal fasting blood sugar; high alimentary rise and rather rapid fall; low threshold.
- D. Same as C except more gente curve; extraordinarily high alimentary rise of capillary sugar.

Case 5. A man aged 45 was seen first in March, 1927. His complaint was weakness. He stated that he had had thirst and frequent urination for 2 weeks at which time sugar was found in his urine. Also, sugar had been found in his urine 21 years ago following an injury. He had had many urine examinations in the interim in which no sugar was found. He had been on a diet a great deal of that time. He is very nervous and has had "sinking spells"; is very much worried about his diabetes. There is no history of diabetes in his family but his

sister has benign glycosuria. He is very apprehensive; he fainted when his blood was taken. Skin, slightly icteric. Blood pressure, 140 systolic and 90 diastolic; tendon reflexes, exaggerated. The urine showed a trace of albumin and sugar with leucocytes and Gram-negative bacilli in the sediment. The Wassermann reac-

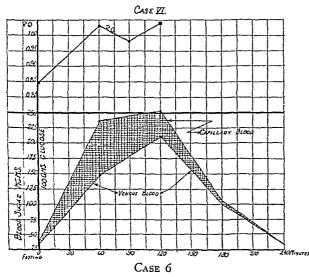

tion in the blood serum was negative. There was decreased liver function as shown by several tests; serum contained 3 van den Bergh units of bilirubin. Cholecystographic study showed unmistakable evidence of delayed gall bladder function. The blood cholesterol was 192 mg. Leucocyte count, 5000. Diagnosis: non-diabetic glycosuria. He is vastly improved (especially his menţal state) so that he is able to work every day. He still has his urinary infection. His fasting blood sugar is always normal while on an unrestricted diet. His weight was 132 and later 140 lbs.

Normal fasting blood sugar; low threshold; olimentary hyperglycemia.

Case 6. (Dr. Carl F. Cori and I were privileged to study this patient through the courtesy of Dr. S. A. Munford of the Clifton Springs Sanitarium and Clinic.) A woman of 55 who has had "mental lapses," attacks of blurring of vision several times daily for the past six years. These attacks were relieved by the ingestion of carbohydrate food. The diagnosis of hypoglycemia had been made three years ago, and stortly after this a partial pancreatectomy had been done by Dr. Finney at the Johns Hopkins Hospital. There has been no essential change in her condition since the

Observations two and a half hours after three teaspoonfuls of Karo syrup; she had had food in some form every three hours during the night. Hypoglycemia at the beginning and the end of the tolerance test. Hyperglycemia which was sustained for two and one-half hours after the ingestion of glucose during which time there was wide variation in the venous and capillary blood sugar determinations. Respiratory quotients higher than 1 suggesting conversion of carbohydrate to fat.

operation. She consumes large quantities of carbohydrate food and has gained 40 pounds in the past three years.

#### Comments

None of the cases presented, with the possible exception of case 3, could be considered diabetic. They represent the various types of glycosuria that have been described with the exception of the more common type of renal diabetes. Glycosuria in these cases is usually an incidental finding; a glucose tolerance test shows a certain glycemic reaction which is usually constant for the individual and which is different than the average normal. The case is classified according to the type of blood sugar curve and sugar excretion; the renal threshold may be low, medium, or normal, the alimentary hyperglycemia may be moderate or

extreme and there may be combined types. Such a motley group may be spoken of as benign or non-diabetic glycosuria until the nature of the normal and abnormal carbohydrate mechanism is better understood. Cori and Cori who have done such fundamental and decisive work in this field have recently shown that in adrenalin hyperglycemia and glycosuria the mobilization of liver glycogen is not increased as we had originally been taught but that adrenalin depresses the oxidation of glucose in the peripheral tissues and this is compensated for by an increased storage of glycogen in the liver and by glycosuria.

The frequently used terms, "prediabetes" and "potential diabetes," seem unsatisfactory as they are often applied rather loosely in the light of modern conceptions of the glycosurias. The diagnosis of true diabetes may often have to be deferred until such signs appear as make the classification certain; under such circumstances the term "suspected diabetes" might be useful. An obese person, especially if there is a family history of diabetes, might be thought of as a potential diabetic but such a usage does not seem to be warranted in view of our meager knowledge concerning the pathogenesis of diabetes.

Four of the six cases presented had all had normal fasting blood sugar values during the whole period of observation while on restricted or unrestricted diets. The glycosuria was known to have been present from two to twenty-seven years. None of the patients had so-called diabetic symptoms excepting one (case 1) who had thirst only when he ate excessively. The alimentary rise for the venous blood sugar after glucose varied between 250 and 180 mg., and the blood sugar at the end of two hours was down to the fasting level in only one case; in one it was over 150 mg. on two examinations. The respiratory quotient would seem to indicate normal glucose utilization in this case.

The first curves shown of cases 1 and 4 might at first glance be interpreted as diabetic beecause of the high rise and rather slow fall, but on analysis it will be seen that one patient had a low threshold, in one the diet was restricted at the time of examination and in the other it had been restricted recently. Subsequent study did not reveal diabetes in these cases and probably this reaction is explainable on the basis of the phenomenon described by This author showed that normals or benign glycosuria patients might show a quite typical reaction of diabetes with the glucose tolerance test if they had been on starvation or greatly restricted diet for a few days prior to the test. This he speaks of as hypersensitiveness to carbohydrate. In view of this the necessity of using unrestricted diets upon doubtful patients before they come up for the

examination is quite apparent.

Case 2, a patient with acromegaly, with diabetes insipidus, and a disturbance of carbohydrate metabolism which usually accompanies such cases is rather difficult to analyze. In the first tolerance curve the fasting blood sugar was normal but there was still a moderate hyperglycemia at the end of two hours; in the second, done several months later, the fasting blood sugar was slightly elevated. The respiratory quotient rose but it did not quite reach unity, and the capillary-venous blood sugar difference was evident only in the first ninety minutes of the test. In view of the well known antagonism which pituitary extracts have for insulin and the rather frequent association of acromegaly and true diabetes which has been recently commented upon by John and by Yater, definite conclusions should be reserved. In all probability, however, the removal of a portion of the hypophysis at this stage would cure the defect of carbohydrate utilization.

Case 6 which would probably be classified, dysinsulinism, is included in this series because the curve, with the exception of the hypoglycemic extremes, is similar to some of the others. In this connection, it is interesting that this patient had been told some years ago that she might develop diabetes; probably because alimentary hyperglycemia was found at that time.

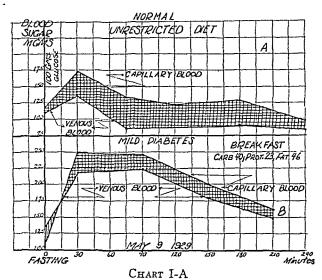

The application of the study of the arterial and venous blood sugar before and after nutriment as was proposed by Hagedorn and by Foster seemed to be a very promising field, as a qualitative index of the amount of glucose removed by the muscles can thus be obtained. Foster showed that the amount of glucose in the cutaneous blood was the same as the arterial which made it possible to eliminate arterial puncture in performing the test. In 1923 Cori and Pucher showed that insulin increased the capillary-venous difference in six of seven diabetic patients. Lawrence found a smaller difference in the capillary-venous blood sugar values of diabetic patients after glucose than was found in normal people. Later Rabinowitch established an average difference in groups of normals and mildly, moderately, and severely diabetic patients of 53, 31, 22 and 7 mg. respectively, one-half hour after glucose. Depisch and Hasenöhrl believe also that the difference between the venous and capillary blood sugar serves as an indirect measuring standard for the amount of insulin produced after the administration of glucose. This method of approach to the problem from the standpoint of diagnosis and possibly prognosis is of great interest, but sufficient work, particularly in longer time observations, on diabetic patients, is still to be carried out before conclusions may be reached. In three of my pa-

tients of non-diabetic glycosuria upon whom this test was done there appeared to be direct relationship between the height of the alimentary rise and the capillary-venous difference, and two in whom this rise was greatest showed the least difference in the receding portion of the curve. This would seem to indicate that possibly there was a great rush of glucose to the tissues, which the tissues handled as well as they could and later settled back for a

compensatory period of inactivity.
It appears then that certain cases of glycosuria aside from true renal diabetes can be definitely separated from diabetes mellitus; they are characterized by a normal fasting blood sugar while taking an unlimited diet, alimentary hyperglycemia which may in some cases be extreme, and a threshold which may be normal or below normal. The blood sugar in two hours after glucose is usually normal but not necessarily so. These patients apparently represent an anomaly of metabolism which may be present in a great many "normal" individuals in a lesser degree. The nature of the disturbance is unknown, though some have expressed the opinion that it is caused by a mild degree of pancreatic insufficiency. This opinion is based upon the experiments of Allen and Wishart who were able to produce a condition of normal fasting blood sugar and alimentary glycosuria in partially depancreatized dogs which later upon overfeeding showed fasting hyperglycemia. It is quite probable that such a condition is present in the extremely early stage of human diabetes. I know of no mention of necropsy reports in the literature on the subject. Dietary treatment is not recommended; one of my patients abstained from large amounts of sweets because he did not like to be annoyed with nocturnal polyuria; this, however, is an unusual symptom.

Unless the clinical diagnosis is perfectly obvious, the following approach to a patient with glycosuria is suggested: In the presence of a positive reduction test it can usually be assumed that the reducing agent is glucose, except during pregnancy and lactation. Alkaptonuria and pentosuria are extremely rare. there is any doubt the phenyldrazin or the fermentation test may be applied. Inquiry as to the character of the diet is carefully made. If the fasting blood sugar is normal it is repeated several times while the patient is eating everything in abundance; if it remains so, i.e., less than 120 mg, then a glucose tolerance test may be of help. If the fasting blood sugar exceeds 130 mg. in patients without hyperthyroidism, uremia or infection, all of which can usually be quickly eliminated, then it may be assumed that the glycosuria is one of diabetes mellitus. It is not uncommon for cases to be under observation for months before a diagnosis can be

safely reached. It is in these border-line problems that some help was anticipated from the use of the study of capillary-venous blood sugar difference and the respiratory quotient. The former does not seem to meet the requirement because this difference is not sufficiently decisive as is demonstrated in Charts I and II as well as the observation of other workers.

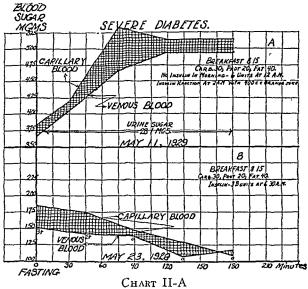

Normal response to glucose; sustained capillary venous blood sugar difference (about 35 mg.) for 3 hours.

#### CHART I-B

Typical diabetic curve; fairly well sustained capillaryvenous blood sugar difference (15 to 25 mg.) for 3 hours and a half.

The respiratory quotient has not been applied sufficiently to afford definite value. In glycosuric patients with obesity and possibly those with arterial hypertension, the presumption is that they have diabetes. It would seem

Typical curve of severe diabetes; capillary-venous blood sugar difference greatest at 75 minutes.

#### CHART II-B

Capillary-venous blood sugar difference greatest in the first part of the curve.

then that every patient with glycosuria should be thought of as a diabetic until the diagnosis is definitely disproven; but that he should not be treated as a diabetic until the diagnosis is made because with dietary treatment the opportunity of making an early differential diagnosis may be lost. The fasting blood sugar may be normal in an early case of diabetes mellitus and it is only upon examinations at frequent intervals that fasting hyperglycemia may be disclosed. It seems then that the determination of the fasting blood sugar is the most dependable method of differentiation of glycosurias from the clinical standpoint.

#### DISCUSSION

Dr. J. R. Williams, Rochester: We have recently developed a new method of clinical study in which the laboratory tests are interpreted in the light of their real significance. It is based on the following premises which have been worked out experimentally in my clinic. The average normal individual eats from 300 to 800 grams of sugar-forming food in a day. One unit of insulin will cause the utilization of four grams of glucose. The healthy body makes insulin as it is needed. Therefore the normal individual makes from 75 to 200 units of insulin daily as is quired. An individual who cannot make 75 units of insulin daily has a dificiency or diabetes. He will show this defect in proportion as his body fails to make insulin. The amount of glucose which a diabetic can utilize in a day can be determined by putting him on a

test diet of known glucose yielding value. from this factor there be subtracted the amount of sugar excreted in the urine, one can determine the amount of glucose retained in the body and presumably utilized. If this figure be divided by four, the number of units of insulin made by the individual can be learned. This is called the insulin coefficient of the patient. If he be given insulin therapeutically it must be subtracted from the amount required for the utilization of the food. The principles here involved are very briefly stated. The details will be presented elsewhere in form adapted to clinical use. This method, which may be called the insulin coefficient method, enables the clinician to not only determine accurately and satisfactorily whether or not his patient has diabetes, but also to measure with precision its severity. By its use one can determine the influence of compli-It is well known that infections For example the insulin codestrov msulm efficient is a far better method of judging the condition of a surgical diabetic than is the leucocyte count or the temperature curve Most patients are being given far too much insulin, the dose being wrong both as to quantity and time of administration. This method enables one to work out the proper dosage. It is the only method which enables the clinician to compare the treatment of one clinic with that of another and to evaluate the various remedies which from time to time are proposed as substitutes for insulin

#### THE EYE AS AN INDICATOR OF SYSTEMIC DISEASES

By L. L ALBERT, M.D., YONKERS, N. Y.

THE general practitioner is likely to pay insufficient attention to the eye as an indicator of systemic disorders, yet the detection of most eye symptoms is within the power of the doctor without the use of special technical apparatus

The doctor finds his patient in coma jective examination of the eyes may give him important clues as to the cause If dependent upon organic brain disease there may be choked disc, mydriasis and deviation of the eyes If due to cerebral hemorrhage there may be miosis, inequality of the pupils and conjugate deviation. With increased intracranial pressure there may be dilated pupils If the coma is due to uraemia, an albuminuric retinitis may be found. When the coma is due to alcoholism, there may be dilatation of the pupils and paresis of the external ocular Poisoning by opium and its derivatives usually causes extreme miosis Atropine and its congeners give marked dilatation Soft eyeballs are invariably associated with diabetic coma

The eyebrows and eyelids may give valuable evidence of the causes of the patient's ill health My voedema and cretinism give rise to swelling of the eyelids and loss of the outer third of the eyebrows Leprosy frequently attacks the eyelids, producing anesthetic skin areas, loss of the lashes and eyebrows, deposit of tubercles under the brow and deformity of the lids Uneven loss of the eyebrow hair should arouse suspicion of late secondary syphilis

Edema of the lower lids directs attention to three common conditions, nephritis trichiniasis and arsenical poisoning Nephritis is the most common Edema of the upper lid is found in elephantiasis Pain on motion of the eyeball is an additional diagnostic symptom in trichiniasis Edema may also be dependent upon cardiac disease and mumps A careful inspection to rule out styes, furuncles and other local

diseases must be made before offering a final opinion as to whether or not edema is due to systemic disturbance.

Exophthalmos, or a protrusion of the eyeball from the orbital cavity, is observed accompanying orbital tumors, injuries, dilatation of adjoining sinus cavities, arterio-venous aneurism, thrombosis of the cavernous sinus, hyperthyroidism and sometimes chronic nephritis and acromegaly.

Exophthalmos, or the recession of the eyeball into the orbital cavity, is commonly seen in the aged, in the extremely emaciated, and in some cases of orbital injury and cholera.

Scleral jaundice is found most commonly in association with biliary obstruction due to gallstones, hepatic catarrh or pancreatic malignancy. A pseudo-jaundice of the sclera is observed in various blood diseases where hemolysis of the red cells occurs, such as in simple anemia, chlorosis, pernicious anemia, severe primary hemorrhage and yellow fever.

Conjunctivitis occurs in a good many infectious diseases. Cerebrospinal meningitis, diphtheria, erysipelis, gonorrhea, influenza, measles, scarletina, typhoid, typhus (the so-called "rabit-eye"), varicella and yellow fever are commonly complicated with catarrhal or purulent conjunctivitis.

Bilateral corneal scars suggest congenital syphilis, altho disease of the teeth, myxoedema and cretinism, leprosy, malaria, pneumonia, scarlet fever, varicella and rickets may also cause a keratitis or corneal ulcer.

Early cataract, the traumatic excepted, should lead to further investigation for diabetes.

Syphilis, the rheumatic arthritides, gonorrhea, tuberculosis, gout, diabetes, and acute infectious diseases may cause an iritis. Iritis, however, is also very often a complication of local infection originating in the apices of the teeth, crypts of the tonsils, nasal accessory sinuses, etc.

Double vision or muscle paralysis should make the physician again suspect luetic disease. Patients acutely ill and showing signs of diplopia should call to mind encephalitis lethargica and possible botulism. Cerebrospinal meningitis, diphtheria and influenza may cause pareses of the extrinsic ocular muscles with resultant strabismus and ptosis.

Nystagmus may be due to eye strain, hysteria, labyrinthine disease, meningitis, multiple sclerosis, encephalitis lethargica or occupational disturbances such as "miner's nystagmus." A pseudo-nystagmus with regular twitchings in lateral excursion of the eyes is found in hereditary ataxia.

Without loss of consciousness, the pupils may be dilated in either cocaine or atropine poisoning. They may be unequal in luetic disease, aortic aneurism, thoracic tumors and pulmonary tuberculosis. Inequality of the pupils, irregularity and loss of light reflex, as a rule, mean neuro-syphilis.

Yellow vision suggests santonin poisoning, while digitalis occasionally gives a patient green vision.

Loss of vision, partial or complete, is most commonly due to increased intracranial pressure, disease of the nasal accessory sinuses, or drug poisons such as alcohol, tobacco, chloral, iodoform, lead, arsenic, nitrobenzol and anilin. Errors of refraction are purposely omitted. Loss of vision in these cases is due to choked disc, optic neuritis, optic atrophy or retrobulbar neuritis.

Retinitis and choroiditis are usually manifestations of such constitutional diseases as nephritis, diabetes, syphilis, arterio-sclerosis, leukemia, orbital tumors, the anemias, septicemia, miliary tuberculosis and scurvy. The appearance in albuminuric retinitis and diabetic retinitis are pathognomic of these respective conditions.

Optic neuritis and optic atrophy are the results of pathological conditions of the brain or its envelopes, of syphilis, aneurisms, sinus infections, drug poisons as above enumerated, acromegaly, sinus thrombosis complicating mastoiditis, diabetes, hydrocephalus, meningitis, myelitis, paresis and tabes, amaurotic family idiocy, and excessive sexual intercourse in men

We see therefore that the most common sytemic conditions which may give rise to ocular symptoms include syphilis, tuberculosis, rheumatism, nephritis, diabetes, sclerosis, cardiac affections, diseases of metabolism, chronic and acute intoxications, infectious diseases and affections of the nervous system. It is no exaggeration to say that this list covers a great part of the practice of medicine. The general practitioner from his physical examination should be able to detect and properly evaluate most of the above enumerated common pathological conditions of the eye. In all cases where any doubt exists as to the correct diagnosis the trained opthalmologist should be consulted. Fine points in the examination of the fundus should be left to the specialist, but the general practitioner should acquire the habit of examining the entire eye including the fundus of all his cases. In this way he often will make a correct diagnosis which otherwise easily might be overlooked.

#### OCULAR TUBERCULOSIS STILL A COMPARATIVELY UNCOMMON DIAGNOSIS IN CLINICAL OPHTHALMOLOGY\*

By MACY L. LERNER, M.D., ROCHESTER, N. Y.

IT IS with some hesitancy that I approach the discussion of this important subject of ocular tuberculosis. It is almost impossible to cover all its phases in the brief time allotted to me.

My interest in this subject dates back to about eight years ago when I had the opportunity to do some experimental work on rabbits' eyes at the Phipps Institute, Philadelphia, Pa., under the direction of Drs. Paul Lewis and Bertha Haessler. The slit-lamp and corneal microscope were used by us daily after the injection of a culture of tubercle bacilli into the rabbits' eyes and my part was to observe the clinical course of the disease and make notes of the slit-lamp findings. We could not find tubercles but we did see infiltration of the cornea, engorgement of the iris bloodvessels, numerous floating cells in the anterior chamber, rapid circulation in the capillaries and vascularization of the cornea. Of course, at that time we could not interpret much that we saw. It was really pioneering with the slit-lamp and only after I had a course with Professor Koeppe years later, did I fully appreciate the original studies. The clinical picture of those rabbit eyes impresesd me and I began to compare it in my mind with the many obscure chronic inflammatory ocular affections observed in the clinics. I studied these cases from every standpoint and concluded that focal infection in many of these cases is only a contributing cause rather than the real source of the trouble.

When we remove a suspected focus of infection and the clinical course of the ocular disease, is somewhat mitigated, as a rule we accept the focal infection as the etiological factor. Too often we do not consider that perhaps other factors, defensive agencies in the body, might have been responsible for the improvement and that the focus of infection is, after all, not the original cause of the ocular affection. But when it comes to a consideration of tuberculosis as the cause, the physician in ophthalmology is more skeptical about its possibility and is willing to make that diagnosis only if he sees abundant tubercles or terminal tuberculous pathology.

It is my feeling that more than anything else we should suspect tuberculosis in any chronic recurrent ocular infection and only after exclusion by complete and thorough studies, then focus our attention to focal infection and other remote etiological considerations. I feel that our patient would gain more and our knowledge of this important subject will be modified. Perhaps then our American figures will compare more accurately with the figures of German literature, as to the incidence of clinical tuberculosis and the fre-

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y., June 6, 1929.

quency of focal infection in disease of the eye. The so-called "doctrine of focal infections" is fairly ancient. Benjamin Rush more than one hundred and fifty years ago described the cure of disease by extraction of decayed teeth. It seems to me that this subject of focal infection has gone too far in all branches of medicine and much too far in ophthalmology. I am sure that very few of us would be willing to have the sphenoid explored with the hope of modifying a chronic uveitis before trying perhaps to improve our general health by instituting an anti-tuberculous

regime.

I do not wish to be misunderstood as to my stand on focal infection. I have repeatedly urged the removal of badly infected tonsils and teeth and have gone so far as insisting upon prostate massage in doubtful cases. In one of my recently published articles I stressed the importance of searching for remote foci of infection. But all these considerations must come last and tuberculosis first.

Often we see a patient with a chronic inflammatory process in his eye lasting from one to two years. His tonsils and most of his teeth are removed perhaps and the antrum explored and a few corrective nasal operations performed but still our patient wanders from clinic to clinic, office to office, begging for relief, when the whole trouble from the beginning was a tuberculous affection which could not be demonstrated either by x-ray or with the ophthalmoscope or other ordinary methods. I am sure the chronicity itself should cause suspicion as to tuberculosis.

Tuberculosis of the eye is rarely a primary condition. It is in most of the cases secondary to a focus elsewhere in the body. Jackson states that a tuberculous focus can exist in the body quiescent but quite able to originate active disease for an average life time. Miller maintains that tuberculosis is a very much more important cause of iridocyclitis than is ordinarily thought and Wilmer and Verhoeff are convinced that ordinary scleritis and keratitis are due to tuberculosis, Derby agrees with Verhoeff and asserts that the American statistics on tuberculosis of the eye, 10%, are rather low, whereas the German, 50%, are perhaps too high. Lowenstein in a recent monograph on tuberculosis of the eye, states that tuberculosis is the cause of 50% of the diseases of the uveal tract. Axenfeld in commenting on his article, remarks that this should be enlightening to American ophthalmologists who attach so much importance to focal infection. Hammon considers ocular tuberculosis a very frequent oc-currence, basing his belief upon the fact that 95% of all adults are affected with tuberculosis.

<sup>1</sup> Gonorrheal Irms, N. Y. State Jour. Med., Oct. 15, 1928.

The diagnosis of ocular tuberculosis will be made more frequently if we oculists look for such infection in chronic cases. In many instances obscure inflammation of the eye is of tuberculous origin. To make a diagnosis may tax one's resources to the utmost and unless one has tuberculosis in mind, the cause may be overlooked. The slit-lamp should be used in all doubtful, suspicious cases. Anemia, loss of weight, slight evening rise of temperature and asthenia may be present in many obscure cases. The internist, pediatrician and other specialists should be called to assist us in establishing a diagnosis in persistent chronic and especially the recurrent type of ocular inflammation. In addition to a complete physical examination, x-ray studies of the chest and other parts of the body should be repeated if necessary. Finoff has removed eyes in which tuberculous processes were demonstrated, the patient showing no clinical or x-ray positive findings. The clinical picture of the eye, however, Dr. Finoff does consider very important in making a diagnosis of tuberculosis. He upholds this statement by his large collection of pathologic eyes showing typical tuberculosis in persons whose physical and roentgenray examinations were absolutely negative.

Of the nine points considered in making a diagnosis of ocular tuberculosis at the Knapp Memorial Hospital, covering a period of 14 years, one, of course, was the clinical appearance of the eye, the other eight being, age, previous history, family history, examination of the system at large, animal inoculation, demonstration of the presence of tubercle bacilli, microscopical examination of the excised portion of the diseased tissue, and tuberculin injection.

a given case, I feel that we should treat our case as tuberculosis and not allow it to drift into chronicity or permit the occurrence of opacities and other pathologic changes which impair vision.

Case I. E. B., female,  $4\frac{1}{2}$  years of age.

Ocular History.—Patient first seen by me at the eye clinic July 2, 1928, when she complained of swelling of the right upper lid. Examination showed a large abscess of the lid. It was treated surgically and patient referred to the pediatric clinic for complete general examination. week later the lid appeared normal but the globe was moderately inflamed. A number of small phlyctenules were present at the limbus. A diagnosis of phlyctenular keratoconjunctivitis was made, and local ocular treatment was prescribed in addition to general hygiene, diet, cod liver oil in small doses and elimination of excessive sweets. July 18, child developed a hordeolum on the same eye (right). July 23, left eye became markedly injected and the phlyctenular keratitis more pronounced.

Patient was treated until the middle of August but the ocular condition grew worse. Both eyes

became involved, the right seeming to be more aggravated. Cornea showed a deep gray-white ulcer and the globe was intensely injected.

Local ocular treatment consisted of atropine 1% in sol. and in ointment, noviform ointment,

calomel powder and mercurochrome.

The child continued to gain in weight but the ulcerative keratitis progressed in spite of all treatment.

Keeping in mind that phlyctenular keratitis is considered tuberculous, I insisted upon complete investigation and studies of this case. The following is the history obtained from the patient and hospital records:

Family History.—One living brother. Mother had been in the mountains for tuberculosis.

Past History.—Child was a full-term baby, 91/4 lbs. at birth, normal delivery and breast fed to nine months. She was in good health up to the spring of 1927. Then she had a spontaneous draining left ear. Discharge lasted six weeks without treatment and ceased; six weeks later, same ear began to discharge again; about three weeks later, the child had measles without apparent complications except for her previously discharging ear. She was admitted however to the hospital for a possible mastoid.

Physical Examination.—Revealed a well-developed and nourished child, up to average weight. There was some swelling on the left side of the neck and tenderness over left mastoid. Heart, lungs and abdomen were negative. berculin test was strongly positive. Blood count, 11,400 W.B.C. and 76% poly; 24% lymphocytes. The pediatrician noted in the record that although clinically the lungs were clear, he suspected tuberculous infection either in the glands or ears If we can get five points of the nine proved in and advised x-ray of chest for tuberculosis and to examine ear discharge for tuberculosis.

X-ray Report.—Stated that there was some haziness in the left chest from the level of the first to third anterior ribs and a questionable slight infiltration just outside the right hilum at the level of the third anterior rib. The roentgenologist was not willing however, to make a diagnosis of tuberculosis and requested repetition of films.

Laboratory Studies.—Nose, throat and vaginal cultures were negative; urine showed trace of albumin and moderate number of W.B.C. sermann and Kahn tests negative; smears from left ear for tuberculosis negative.

May 29, 1927, left mastoidectomy was performed and an enlarged gland from behind mastold was also excised. Pathological report showed connective tissue, muscle and fat infiltrated by numerous leucocytes and mononuclear cells.

In June, patient developed paronychia of the

left thumb requiring operation.

In July, patient came to me and was treated as described until the middle of August. Upon my request, the patient was then sent to the Monroe County Tuberculosis Sanitarium for study and observation. Their report to me stated that the tuberculin test was strongly positive and the x-ray showed increase in hilum shadow on the right with calcification at both hila. Their diagnosis was hilum tuberculosis. They also obtained a history of tuberculosis in the mother whose physical examination showed active pulmonary tuberculosis. The child was in the mother's care.

The patient was treated on the usual antituberculous regime. A secondary mastoidectomy on the left side showed pus with tubercle bacilli. A later report stated that the child was overweight, well nourished and the eyes had cleared

up completely.

Summary of Case .-

 Child had a left chronic discharging ear for more than one year and had been admitted to hospital for operative procedures four times in one year.

2. Operations dealt with purulent infections in different parts of the body, ear, finger and eyelid.

3. X-ray studies of the chest were by no means negative as to tuberculosis from the start but a definite diagnosis could not be reached.

4. Child developed a severe degree of phlyctenular keratitis which did not improve under ordinary general care, diet or local treatment.

6. Child developed a severe degree of ulcerative keratitis extending from a broken down phlyctenule.

7. There was a definite history of tuberculosis

in the mother.

8. Monroe County Tuberculosis Sanitarium report stated that the mother had active Tuberculosis.

9. Child had been in contact with the mother all the time.

10. Tubercle bacilli were found in the pus of the secondary mastoid.

Case II. M. H., male, age 10.

September 25, 1925, reported to me with a history of having an inflammatory ocular condition for more than six months. He was treated by capable ophthalmologists but without improvement.

Ocular Examination.—Showed three deep ulcers situated in the pupillary area, involving its borders. Pupil was small and the globe slightly injected. Photophobia and lachrymation were pronounced, but little pain.

X-ray Examination.—The report of the examination, made at my request was, right and left hilus areas, moderately infiltrated. Calcifications observed within both hilus regions. Bronchial markings somewhat exaggerated on both sides, the greatest amount of exaggeration being on the left side in the upper lobe. Right pulmonic area, a few small, fine densities resembling tubercle, observed within the upper lobe region, close to the aortic outline. Left pulmonic area, a few fine

mottlings observed scattered along bronchial tree trunks. The upper lobe presented a slightly hazy appearance.

The roentgenologist considered the lesions de-

scribed of an early tuberculous process.

The patient was taken out of school and an anti-tuberculous regime instituted in addition to local ocular treatment. The patient made a perfect recovery and when last seen on December 25 for refraction, he had 6/6 vision in the right eye with a  $+1.25+1.25\times90$  and 6/12 in the left with +150 sph. Patient had no recurrence of the trouble.

Outstanding facts in this case are: pulmonary tuberculosis revealed by x-ray only and ocular complications of ten months duration.

Case III. S. N., female, aged 9.

Past History.—Scarlet fever at one year, measles and whooping cough five years ago, also had chicken-pox.

Ocular History.—Mother stated that the girl had been suffering with sore eyes since 1923. I examined her for the first time in December, 1926, and found 4 small corneal ulcers involving the pupillary borders and extending somewhat centrally. The globe was considerably inflamed. Pupil reacted normally and no other changes were noted. The chronicity, four years duration and intermittency impressed me more than the ulcerative keratitis itself.

Physical Examination.—Report was as follows: purulent discharge from both sides of the nose, several carious teeth, moderately enlarged tonsils, cervical glands slightly enlarged, weight one pound above average, heart and lungs normal, abdomen negative. Throat culture, numerous gram positive cocci (staphy cocci and bacilli). Quite a few gram negative bacilli. Nose—numerous gram positive cocci in pairs (pneumos). Ear examination—negative. Tonsils subacutely inflamed, hypertrophied, T. and A. advised. Blood examination—Wassermann negative; R.B.C. 4,640,000, white 9100, hemog. 80%. Urine examination—negative.

The tonsils were removed, teeth corrected. Ocular condition improved but in a short time, the trouble recurred.

I requested another physical examination of the chest and x-ray studies.

January, 1927, gained two pounds. Chest examination showed upon percussion dullness in intrascapular region.

Stereoscopic films of the chest showed definite exaggeration of the bronchovascular structure in both upper lung fields but more in the upper left; lower fields quite clear. The roentgenologist considered these findings definite evidence of a tuberculous infection. My feeling was then that the x-ray findings of the lungs plus four years duration of an ocular inflammation associated with ulcerative keratitis were sufficient to make a diagnosis of tuberculous keratitis. I sent the

girl to the Monroe County Sanitarium and received the tollowing report from Dr. Bridge:

Child's family history: Father had a chronic cough. One cousin of child's mother had tuberculosis. Patient had ordinary childhood diseases and repeated attacks of bronchitis. No history of exposure to tuberculosis with the exception of one week's stay with her mother's cousin who had advanced tuberculosis. Child had ulcers of the eyes at intervals for the past four years, under treatment of different ophthalmologists.

Present illness—tires easily, recently gained weight, good appetite, constipated, neither listless nor restless. Has headaches after studying, also frequent colds up to about one year ago,

now has an occasional slight dry cough.

Physical examination—Shows slight increase in tracheal whisper over the vertebral spine and a few high pitched rales at the right base. Neck shows many small palpable nodes on both sides; is one-half pound under standard weight.

In February, x-ray showed left lung with many small calcified areas above second anterior

rib.

Diagnosis. Hilum tuberculosis.

Progress notes.—As follows: there was a gradual disappearance of the signs, at the right base but they tended to recur. Patient was discharged September, 1927, able to go to school, five pounds overweight, in excellent physical condition and the eye completely cleared up. When seen by me last, the eye was perfectly quiet, globe white, a faint macula was observed at eight o'clock in the left eye. Fundi were normal. Vision was 20/20 in the right eye with a  $+150 \times 75$  correction and 20/50 in the left eye with a correction of  $+2.25 \times 90$ .

Summary of Case .--

1. Ocular disease of four years duration treated by several ophthalmologists.

2. Eradication of all foci of infection did not

benefit ocular condition.

3. Definite history of tuberculosis in the family, obtained rather late in Sanitarium.

4. Positive tuberculous x-ray findings con-

firmed by Tuberculosis Sanitarium.

5. Physical findings reported negative first time but proved positive on two later examinations.

6. Complete and permanent ocular recovery only after a stay in the Tuberculosis Sanitarium.

Case IV. G. C., female, aged 27.

Report of Case.—Consulted me first September, 1924. Her complaint was blindness in the right eye and poor vision with opacities in front of her left eye. She stated that her ocular trouble dated from 1920, when she suffered first from dizziness, became irritable and sleepless and began to see specks before her eyes, especially the right eye. The sight in the right eye was gradually lost. She had no pain. She was treated by

an ophthalmologist and by a general physician for neurasthenia and nephritis. Her tonsils and several abscessed teeth were removed. She had worn glasses all her life but had recently discarded them.

Upon examination I found the right eye deviated inward about 30 degrees. Cornea and conjunctiva clear. Anterior chamber shallow. Pupil about 2½ mm. oval, with grayish borders and synechia at seven o'clock, reacted to light very sluggishly. Left eye normal in appearance and pupillary reactions were perfectly normal.

Visual acuity.—O.D. not even light perception. O.D. 6/12-2.

Ophthalmoscopy.—Right eye, media; red reflex in pupillary area. Vitreous, full of shred-like opacities floating freely in all directions. Iris showed post-synechia. Anterior surface of the lens covered with pigment and showed evidence of old adhesions. Under atropine, pupil dilated irregularly, and the iris bulged forward. Fundus details could not be obtained.

Left eye, media; numerous vitreous opacities floating freely in all directions. The opacities appeared to be membranous in character. Fundus details could not be seen clearly on account of opacities.

Complete physical and laboratory examinations were carried out.

Physical Examination.—Negative.

Blood and Urine Examination.—Showed nothing abnormal.

X-ray of Teeth and Sinuses.—Negative.

Sputum Examination.—For tuberculosis, negative.

Vaginal Smears.—Showed no g.c. and no pus. All possible foci of infection were considered and eliminated. The ocular condition was about the same. Visual acuity in the only eye fluctuating from 6/15 to 6/12.

A blood chemistry showed nothing abnormal. Another chest examination revealed that she had a few nonpersistent rales posteriorly. A second x-ray of the chest showed slight haziness at the second and third interspaces toward axilla, not definite enough to make a diagnosis of tuberculosis. Her temperature was 99, pulse 80, b.resp. 20, B.P. 104/88 and weight ranged between 109-112 lbs.

Corneal Microscopy.—Showed a Koeppe nodule at the iris border of the left eye. This nodule was also observed by Prof. Koeppe himself, who was kind enough to come to my office and check up on my observation. The suspicious nodule and all negative physical and laboratory findings left doubt in my mind as to the true etiology of the case. I was not satisfied that focal infection could be the cause, because none could be found and all possible ones had been eliminated years ago.

A careful history was obtained and studies

renewed:

Family History.—Upon detailed questioning I learned that there was tuberculosis on the father's side and that one sister (younger) became blind in one eye in a similar manner as our patient.

Personal History .- Revealed that she had all childhood diseases and frequent respiratory infections including bronchitis with much sputum production. She had occasional swelling of the

inframandibular glands.

I examined her sister's eyes and found that one eye had a pathological process similar to the

blind eye of my patient.

In December, 1927, the patient came to me again, stating that her general health had been good until the previous week. At that time, she began to feel tired, weak and sleepless and for the last four days she had experienced blurring vision in the left eye, associated with pain in the temple. I learned, too, that she had married in 1926 and had two successive pregnancies. During each one, her sight had been improved but only temporarily. Her first baby had died at eleven months from pneumonia. Her second baby was four months old and depended upon breast feeding.

Ocular examination.—Visual acuity OS 6/12. Globe white, pupil round and active. Ophthalmoscopy showed vitreous full of opacities of all shapes and in cloud-like form. Fundus details

could not be seen.

Corneal microscopy. — Revealed gray-white opacities in deeper layers, fine deposits on the crystalline lens and a suspicious gray, round nodule at the retinal pigment border at 4-5 o'clock.

Her vision in the only eye grew worse and on December 31, it was reduced to 6/60 (the only eye). Patient was ordered to hospital and complete studies renewed. Cultures from the teeth, sinuses, cervix and vagina were made and proved to be negative. Urine, negative. Blood count, normal except for the increase of mononuclears 40%. Nose and throat examination, including x-rays, were negative. X-rays of the chest showed obsolete tuberculosis, diaphragmatic adhesions, calcified hilus lymphadenopathy. Skull, normal. Suggestion of bilateral sinusitis. A pediatrician was consulted about weaning the baby. I urged the mother to rest, gain in weight and wean the child.

In view of the threatening total blindness in both eyes, I requested the otolaryngologist to explore her antra, which in the x-ray suggested sinusitis only. The exploration was done January 5 and the report was that the mucous membrane was somewhat thickened and no other pathology found. Cultures, negative. Sphenoids and ethmoids entirely negative.

'-acuity was The following day patient's v

6/10 an improvement from 6/60. It is certainly improbable that in 24 hours the vision could be improved to that extent when the sinuses showed practically nothing abnormal. On the other hand, the patient had rested one week, gained in weight and the baby was removed from the breast.

The patient has been under my observation She has gained weight and feels well. She retains the 6/10 visual acuity in the only eye and the fundus details could be made out.

Outstanding Points in this Case.—

1. History of ocular affection went back to 1920 with gradual loss of vision in the right eye and beginning failing vision in the left.

2. Recurrent attacks without pain.

Frequent colds and upper respiratory infections.

4. History of tuberculosis in the family.

5. History of similar ocular condition in a younger sister.

6. Koeppe nodules observed twice at two year

intervals and confirmed by Koeppe.

7. Left eye aggravated after two successive pregnancies and nursing baby.

8. Marked improvement of visual acrity after

gaining weight and upon weaning baby.

9. Exclusion of all possible foci of infection without benefit except for the startling improvement of the visual acuity only 24 hours after an exploratory antrum operation.

Case 5. F. T., female aged 26, married, no

children.

Past History.—Ordinary childhood diseases, quinsy in 1923 and attacks of tonsillitis every winter, including the winter of 1927. Since December, 1926, she had been suffering from joint pains. Her physician considered her pains possibly due to the tonsil infection although he told her that she might have rheumatic fever. A tonsillectomy was performed in February, 1927, and three weeks later she began to have blurred vision and dizziness, associated with occasional mild ocular pain. She consulted an ophthalmologist who prescribed atropine and yellow oxide to be used every night.

Patient first reported to me April, 1927. Upon examination her visual acuity was 3/60 in each eye without glasses and 6/12 (rt.) and 6/30 (1.) with her correction, the latter being -300 sph. in the right eye and  $-350 - 50 \times 150$  in the left

External Examination .- Pupils were dilated regularly and were under the influence of atropine. Right globe showed a very mild generalized scleral injection. Left eye showed a mild ciliary flush while the cornea showed deep punctate infiltrations.

Ophthalmoscope revealed typical "mutton fat"like deposits on Descemet's membrane; vitreous had considerable floating opacities; disk although

outlined, showed hazy margins, its color rather hyperemic, retinal veins much engorged, tortuous and constricted at places, arteries appeared thin and some arteriovenous compression was observed; no lesions or hemorrhages were noted in the fundus. Left eye showed descemetitis, more pronounced and vitreous opacities more abundant while disk was very blurry, its edges ill defined, veins much engorged, arteriovenous compression present; no hemorrhages or other lesions could be seen.

Complete medical and laboratory investigation were made in addition to local ocular treatment. The report stated:

Urine Examination.—Essentially negative except for a faint trace of albumin.

Stool Examination.—Negative.

Blood Examination.—97% Hbg., 8000 W.B.C., 70% Pmn., 7% transitionals, 22% lymphocytes, 1% myelocytes, R.B.C. normal; platelets abundant, Wassermann negative.

X-ray of Teeth.—No evidence of infection;

impaction of all the third molars.

X-ray of Chest.—Large masses at each hilus region at location of tracheobronchial lymph nodes; discrete with sharp outlines and of uniform density. Probably this indicates recent or active tracheobronchial lymph node tuberculosis or possibly tumor. No definite evidence of active parenchymatous pulmonary tuberculosis.

X-ray of Sinuses.—Slight clouding of antra.

Blood Culture.—No growth on agar, blood plates, deep tubes or in broth.

Skin Test.—With toxin strept, rheumaticus (Birkhaug), negative.

Intradermal Test.—With 0.0001 gm. Koch's

old tuberculin, slightly positive.

Culture of Throat.-Predominately streptococci; 15% hemolytic, 45% viridans and 50% strepts; neither hemolytic nor viridans, which ferment insulin (strept rheumatica of Birkhaug).

Physical Examination.—Showed a complete flaccid facial paralysis, slight symmetrical enlargement of the thyroid, rapid heart beat, slight eversion of uterine cervical mucosa with moderate amount of white secretion.

Nose and Throat .- No evidence of sinus disease from x-ray or physical examination.

Gynecological Examination.—No evidence of pelvic focus of infection.

Further Laboratory Studies. - Intradermal tests: sterile filtrate of broth culture of strept. recovered from patient's throat, negative. berculin test, 0.0005 gms. intracutaneously showed a red area at the site of injection about 12 hours later,  $.5 \times 2.5$  c.m. in diameter.

Culture of Cervix.—Uteri, no growth in broth or blood agar. Urine culture negative.

Patient was returned to me for ocular treatment. She continued to lose weight (about 10 lbs.), had occasional little spikes of temperature

The chest examination and her pulse ran fast. was as before.

A later x-ray of the chest showed no appreciable change over previous one but the report expressed "possibility of active process at present." Patient complains: no energy, easily tired, occasional headaches, pulse rate 100. metabolism, plus 5.5.

Patient was under my observation throughout

the year of 1927 up to May, 1928.

Corneal Microscope.—With the slit-lamp illumination, showed a bilateral descemetitis more prominent in the left eye. Anterior surface of the right crystalline lens appeared waxy. left one fairly clear. Both irides were clear. Its retinal pigment borders, clear and regular.

The descemetitis in the right eye was much less. Fundus details were fairly clear while the external appearance of the right eye was white. Left eye, descemetitis practically gone, only one or two deposits noted. Fundus details clear. V.OD. 6/9 plus + 4 with correction. V.OS. 6/9 plus + 4 with correction.

In July, patient had an exacerbation of the attack in the right eye. Vision became cloudy, without pain. V.OD. 6/12. V.OS. 6/6-1.

In September.—Considerable deposits were noted on Descemets membrane in the right eye. Fundus details were veiled. Slit-lamp showed numerous white-gray deposits, round in shape on the Descemets membrane, mostly on the temporal side. Capillary circulation very active Iris border normal. No evidence of synechia. Anterior surface of the lens clear.

A diagnosis of bilateral uveitis was made in April, 1927, but the tuberculous nature was only revealed as late as October, 1928. It could not be established by the ophthalmoscopic or slitlamp studies alone but rather on the evidence of x-ray of the chest, general clinical and ocular course-namely, chronicity of the ocular inflammation, its painlessness, general tiredness, lack of energy, headaches, pulse rate of 100. Until she had gained 15 pounds, her ocular picture was fluctuating. Her ocular treatment consisted of atropine 1% ti.d., dionine 5% +i.d., diet, rest, fresh air and sunshine. Impacted teeth were urged to be removed and so done by the patient.

May 18, 1928.—Patient had 6/6 vision in each

With her correction: OD.  $-375 - 50 \times 306/6$ OS.  $-450 - 50 \times 1506/6$ 

Patient had another mild exacerbation and the slit-lamp showed white cotton-like deposits on Descemets membrane. Anterior capsule dotted with yellowish iritic pigment. A suspicious graywhite nodule (Koeppe) noted at seven o'clock.

My reason for not considering tuberculin in the treatment of this case was based on the wise warning from the hospital medical attendants1

<sup>&</sup>lt;sup>2</sup> Strong Memorial Hospital, Rochester, N. Y.

"that tuberculin therapy is too dangerous to be attempted in this acute case, without hospital care and daily observation of the eye for focal disturbance." I am happy to state that the patient is now absolutely free from ocular trouble.

Case 6.-V. M., male, aged 15 months.

Patient was brought to me with a history of an inflammation of the left eye lasting fifteen days.

Essential Points in the History .- First baby, normal delivery. Bilateral otitis media in March, from which he made a perfect recovery. Tonsillectomy in April. Never had ocular trouble before.

Ocular Examination .- Deep grayish white corneal infiltration with marked vascularization The area involved was from the nasal limbus up and including about 1 mm, of the pu-The ulcerative area was studied pillary area. with the slit-lamp and proved to be rather deep. Local treatment consisted of atropine et noviform, mercurochrome, yellow oxide, later-calomel powder and diomine in addition to hot compresses. A restricted starchy diet was given and a complete elimination of candy and other sweets. The ocular condition was somewhat improved but the progress of the ulcerative keratitis was not checked.

Upon my request, Dr. Kaiser made complete studies and reported: heart, lungs and nervous system normal. Blood Wasserman, negative. Urine examination, negative. The boy was wellnourished and developed and somewhat overweight but the tuberculin test was strongly positive.

I then ordered the child to the Lake Shore, to be left outdoors exposed to sunshine and to continue the above ocular treatment and careful diet. It required from two to three weeks only, to get a perfectly quiet white eye with complete healing of the ulcer, leaving only a slight marginal opacity.

Summary.-Two weeks of fresh air and sunshine accomplished a remarkable result while two months of all kinds of eye solutions, powders and ointments showed by aid of the loupe, slitlamp, etc., only a questionable degree of improvement. Only after the child made a perfect recovery, did the happy parents admit to me that the father's brother had active tuberculosis.

The entire case was negative as to tuberculosis clinically and from the physical examination except for the positive tuberculin test and history of tuberculosis in the uncle.

Case 7.-F. O., female, Italian, aged 14.

Family History.-Negative.

Past History .- Had measles when a baby, chorea in 1926, tonsillectomy at ten years and a history of persisting hoarseness since birth.

Ocular History.-First seen by me in 1924 when she came for pain and photophobia in the right eye. Examination showed at that time

four gray-white infiltrations in the right cornea associated with slight bulbar injection. The ocular affection soon became bilateral. The infiltrations in the cornea were deep and more numerous. At times the eye would get quiet and then the trouble would recur. Local as well as general treatment did not influence the disease.

Complete Studies were made and the following reports recorded: nose and throat examination, negative: x-ray of sinuses and teeth, negative; blood Wasserman with cholestrin antigen, as well as the Kahn test, negative; blood chemistry showed nothing abnormal; blood count, Hg. 87%, 4,700,000 R.B.C., 8400 W.B.C., differential white count normal; O.T. test 0.1 mgm., negative; physical examination did not reveal anything abnormal; x-ray studies of the chest showed prominent hilus shadows and exaggerated bronchovascular tree markings but no evidence of pulmonary tuberculosis.

A very careful diet was outlined for her and cod-liver oil prescribed in addition to various ocular treatment including atropine, dionine, calomel powder, holocaine and noviform ointment. She gained in weight and looked well but the attacks would recur and produce more extensive infiltrations. Her visual acuity in the right eye was diminished to 1/60 and the left eye to

6/10.

A diagnosis of keratitis of neuropathic origin was made by me, not because it appeared to me as such but rather from lack of knowledge as to its etiology. Corneal microscopy did not give me more information. It merely showed deep graywhite corneal infiltrations, scattered throughout and an active capillary circulation. Irides were perfectly normal and no deposits were noted.

For four years patient had relapses one after another. We could not succeed in getting the eyes

to stay quiet nor arrest the progress.

I had her sent to the Monroe County Sanitarium November 12, 1928. The report from there stated that the x-ray showed hilum calcification and an area of increased density under the third rib on the left side. O. T. 1/200 and 1/10 mg. negative. Sanitarium attendants, however, expressed an opinion that she had minimal pulmonary tuberculosis. I have followed the case up to date and have learned that her eyes have improved very much since her stay there.

Summary.—The only outstanding findings in this case are chronicity of four years' duration and suspicious x-ray findings of the chest.

Her treatment at the Sanitarium consisted of ultra-violet rays to the whole body plus an antituberculous regime.

#### Discussion

In 1917 Koeppe described nodules in connection with tuberculous iritis. He considers them almost as pathognomonic of tubercular iritis when located in the iris. He states, however, that sympathetic ophthalmia, leprosy, and tropical syphilis must be excluded first, as these nodules are transient in character, appear and disappear within a short period of time. In two of my cases these nodules were definitely demonstrated with the corneal microscope and slit-lamp. One of them I had the fortune to have corroborated by the author Koeppe, himself.

According to Dr. G. S. Derby, these nodules are very common in *low grade uveitis* and it is his belief that they are probably of tuberculous etiology. The nodules histologically are composed of plasma cells, which is consistent with an early stage of tuberculosis caused by the action of a

toxin (Derby).

Dr. C. S. O'Brien recently reported a case of phlyctenular conjunctivitis which he attributed to be due to tuberculosis. He based his conclusion on the pathological findings of a biopsy of a gland removed from his patient. My first case showed tubercle bacilli in the pus and tissue removed at secondary mastiodectomy. A gland was also removed from behind the mastoid region at the first operation and studied microscopically. The findings suggested a tuberculous process. O'Brien's and my case seem to me to throw some light on the etiology of phlyctenular keratitis.

My remaining cases had positive tuberculous x-1ay findings of the chest, positive tuberculin reactions and in two cases a Koeppe nodule was

observed.

Rollet and Colrat are not in favor of tuberculin therapy and are very critical about the published results of this treatment in other countries. They consider it more or less dangerous. In considering the uveal tract, the authors state that these cases are all of secondary origin and that the primary focus of infection is situated in the peribronchial lymph nodes. In their study of more than 100 cases, the authors were able to find at kast 80% evidence of other tuberculous lesions. They contend that the proportion of cases will be increased by the systematic use of radiotherapy in demonstrating trachebronchial adenopathies. T Jey advise local treatment of course, but stress the great importance of general treatment. Their objection to tuberculin is because of the fever eaction and the difficulty of correct dosage. Some teaching institutions mention it only as a remedy but do not advocate it seriously, nor do they outline the mode of administration so that the average ophthalmologist would feel safe in administering it without making his patient worse. Thera is also a good argument that the benefit obtained from tuberculin is due to the action of a foreign protein rather than to any specific qual-

\_\_\_\_

ity of tuberculin. It may fairly be doubted whether it has conferred substantial advantage in the fight against the disease; whether at least as much and possibly more might not have been accomplished by the same general measures as have proved relatively successful in the control of pulmonary tuberculosis. In a recent article by Dr. Wilmer on treatment of ocular tuberculosis with tuberculin, he reported in detail a number of cases that were improved with tuberculin but I noted that most of his patients were treated with thyroid and other remedies in addition to the regular anti-tuberculous regime. So here again it is difficult to evaluate from the report exactly what was responsible for the mitigation of the disease.

The human body tends to cure itself of tuberculosis.—A sanitarium, climate, good food, rest, physicians and kindly nurses are only aids in this tendency. These are the words recently put forward in a well written article by Dr. A. H. Crisp of Denver. When a cure is completed then, the part played by the physicians is to create conditions favorable to the healing influence of nature, rather than to administer specific treatment having definite power to combat the disease.

My feeling is that there is no specific treatment for tuberculosis. Ocular tuberculosis does not differ from tuberculosis anywhere else in the body. In my experience it is just as easily managed and benefited by giving nature a chance to build up the patient. Tuberculin, while perhaps very beneficial as attested by brilliant reports in literature, is very dangerous in the presence of

active lung involvement.

### Conclusions

- 1. Sanitarium treatment and an anti-tuberculous regime benefited my patients and cured most of them.
- 2. Ocular tuberculosis is not sufficiently recognized either in ophthalmic clinics or in private practice.
- 3. Focal infection although a frequent etiological factor in ocular disease is too much over-emphasized and because of that, tuberculosis not sufficiently stressed.
- 4. Complete ocular studies, including slit-lamp microscopy, x-ray, laboratory and expert medical advice from other departments of medicine are very essential in making a presumptive tuberculosis diagnosis of the eye.
- 5. Sunshine, fresh air, good food—in other words, an anti-tuberculous regime—perhaps would give us as good results as tuberculin, with less danger and risk to the eyes.

### MALIGNANCY OF THE TONGUE ON A LUETIC BASE\*

By J. ARNOT MAC GREGOR, M.D., NEW YORK, N. Y.

' HAVE attempted to gain your interest at this time through a study of twenty-five patients that gave a history of syphilis with positive serology, and later developed carcinoma of the tongue, in its adjacent structures, or in both.

A large percentage of these patients were referred to the syphilitic clinic for forced antiluetic treatment as a preparatory step to a surgical

operation.

For some time I have been so impressed with the poor response and the too frequent untoward effects of arsenicals and heavy metals in this type of case that I finally went over more than six thousand syphilitic histories to assemble the information and analyze the notes made at the time of treatment.

It is not my purpose to discuss the pros and cons of surgery, endotherm, radium or x-ray therapy in such cases for this is outside of my jurisdiction. However you will presently see that I have been interested in following the cases be-

yond the syphilis clinic.

In selecting the group no consideration was given to the various forms of so called glossitis, leukoplakia, verrucous, or papillatory lesions of the tongue or adnexa in well established luetics. Nor were those included with negative scerology and a definite clinical diagnosis of carcinoma.

The diagnosis between syphilis of the tongue and epithelioma is most important. It may be well at this point to dwell briefly upon the usual phenomena of malignancy of the tongue, and as the English authorities "Marshall and French" have outlined it so well I quote from their volume on "Syphilis and Venereal Diseases."

 Epithelioma is more circumscribed, forming a hard vegetating tumor with everted borders generally situated on the side of the tongue:

It bleeds easily when irritated:

3. The saliva and breath are very foetid:

4. There is early fixation of the tongue and difficulty protruding it:

5. There is more pain, especially of a neurologic character:

6. The glands soon become infected:

7. The age of the patient is usually between fifty and seventy:

8. It may occur on the undersurface of the

9. It is often preceded by leukoplakia, which may be found on the tongue or on the inside of the cheeks.

Many of the patients in this study gave a history of known irritation from the sharp edge of a tooth, while others learned of an ulceration during a visit to a dentist. Yet it is difficult to

Read before Clinical Society meeting, New York Skin and Cancer Hospital, October, 1929.

state with marked assurance that one or all of the cases started as a definite luctic gumma and under the influence of trauma or local irritation became degenerated into a progressive epithelioma. It may be that the lesion had its initial character as a neoplasm in an individual who was also a syphilitic.

The lesions varied in size, shape, and location. In some cases it seemed that the lesion was confined to the tongue, while others extended into the adjoining tissues. The early records lacked some detail but seven cases showed ulcerations along the right border, three along the left border, and two on the tip of the tongue. Single lesions predominated, a small number were multiple, and in others the whole tongue and floor of the mouth were involved in a great sloughing mass. Those on the dorsum of the tongue took the form of a deep fissure, but the border lesions were more of a punched-out type, corresponding to the sit of one or more ragged teeth. In several instances there was an accompanying glossitis, three showed a definite leukoplakia, and one was of a verrucous type. One case stated that a dentist first noticed a "lump" when the patient went to consult him about a painful tooth.

The duration of the malignant lesion from the time it was first noticed until the receiving of antiluetic treatment varied from three months to over one year, with an average of seven

months.

In turning aside to the syphilitic phase of the subject I am able to report that thirteen of the cases gave a definite history of a chancre on the penis, five a general rash following the initial lesion, five having gonorrhœa and syphilis, and the remainder of the twenty-five did not remember any definite lesion. They received some antiluetic treatment previous to the development of the mouth lesion. Of the thirteen giving a history of chancre twelve had received local treatment (wash or powder) at the time of first infection, but no arsenicals or heavy metals until coming to the syphilis clinic. The length of time from the initial luctic infection until receiving antiluctic treatment was as follows:

1 case 12 years, 6 cases 25-30 years, 6 cases 40-50 years.

It will therefore be seen that either the normal resistance of this portion of the group must have been above the average or the spirocheta were not extremely virulent, or both in order that the patient could carry on from one-quarter to onehalf a century without any manifestation of disease and then only to appear because of intensive irritation.

All the group belonged to the white race, twenty-two males, three females, three single (men). The ages ranged from thirty-eight to seventy-six, thus four under forty-five, forty to forty-five, five from fifty to sixty, and ten over sixty.

In following the twenty-five cases beyond the luetic clinic it was found that they divided them-

selves into classes, thus:

A.9 (36 per cent) died at the time of surgical operation which constituted excision of the tongue, or died within one year of the operation.

B.12 (48 per cent) were discharged from the surgical clinic as inoperable. The twelve were made up as follows: 5 no available record, 4 have since died, 3 alive but discharged within the last three months.

C.2 (8 per cent) under observation. No help from treatment.

D.2 (8 per cent) referred to the surgical clinic. Failed to report.

I would here like to give a brief history of

three unusual cases:

Case Number 727, male, white, married, age 62, had a history of chancre 1893. He received local wash until 1922 (29 year interval) when he came to this hospital with a verrucous like plaque on the dorsum of his tongue. There was a question of diagnosis so as a therapeutic test the patient received mixed treatment (mercury and potassium iodide) by mouth three times daily for four months followed by five arsphenamines. There was only slight change in appearance, size, or consistency of the tongue lesion although patient had improved in general health. The blood wasserman was four plus. The right half of the tongue was removed (surgically) on January 26, 1923. It healed satisfactorily. The patient was later continued on antiluetic treatment until April, 1924—over one year—receiving thirty-five arsphenamines and forty mercury salicylates.

A one plus wasserman was recorded in the fall of 1924, and about this time a growth appeared on the base of the remaining portion of the tongue. In November, 1924, a complete excision of the remaining portion of the tongue was made. A few days later a paracentesis was necessary. The patient had a much enlarged liver, general carcinematosis and died January 1, 1925.

There was evidently metastitic involvement of the liver and it is in such cases that one authority points out that arsenical and vigorous antiluetic

treatment may produce serious results.

Case Number 3466, age 50, male, white, married and referred to the clinic June, 1929. He then showed a deeply fissured ulcer along the right border and dorsum of the tongue. The surrounding tissue was indurated and the glands of the neck firm and enlarged. The tongue was very painful, burning, tingling, with considerable sloughing of necrosed tissue. The breath was foul smelling. The patient was unable to swallow solid food, had lost considerable weight and looked ill. I believed this case inoperable but

retained him in the clinic longer than usual to see if any of the various antiluetic agencies might by chance ease the pain or negotiate healing. He received seven arsphenamines, seven bismuths, seven mercury injections, with continuous gradually increasing doses of potassium iodide by mouth. The first two or three arsphenamines seemed to ease the condition slightly but he soon became worse and progressed so rapidly that on being referred back to the Surgical department he was sent at once to a home for incurables.

Some authorities believe that definitely or persumptively inoperable malignancy associated with syphilis should be treated for syphilis either as a therapeutic test, to give the patient a chance, for an error in diagnosis would provide or secure for him a certain amount of tonic or non-specific effect and improvement in well-being during his remaining days. My experience has differed from I have found that the syphilitic patient. without any sign of malignancy, past the fiftyyear mark does not bear arsenicals well, especially if many years have elapsed between the contraction of the disease and the receiving of treatment. If one must give the non-malignant syphilitic very moderate treatment still more care must be used in a syphilitic, whose system has added the burden of an inoperable carcinoma.

Case Number 3576, male, white, married, with a history of chancre and gonorrhœa about fortyfive years ago. Some ulcers developed on his tongue about ten years ago. They were healed from time to time by the use of caustics. registration in the syphilitic clinic September 9, 1929, most of the posterior dorsum of the tongue showed a verrucous like plaque, while it was surrounded by a grayish leukoplakia. The midanterior area showed an excavated lesion with pearly indurated border and covered with a foetid secretion. The tip of the tongue gave the appearance of a mild glossitis. On this date the blood wasserman was two plus. He received two arsphenamines (average 0.2 grams), one bismuth followed by four arsphenamines, then potassium iodide and mercury by mouth. Allonal tablets were given to ease the pain and a mild mouth wash locally. On October 1st a new glossy indurated lesion appeared near the base of the tongue and on the floor of the mouth. I believed this malignant although it may have been only part of the syphilitic process since he developed a marked general rash two days after the last arsphenamine. I decided this was arsenical and started injections of sodium thiosulphate at once. Because of the progressive painful tongue condition he was referred to the surgeons and hence into the hospital. In a day he became delirious with a temperature well over 103 and the rash blossomed out into a well-established exfoliative dermatitis. During late October and early November the exfoliation gradually subsided and the temperature slowly returned to normal, the adema lessened in the tongue, and the sloughing decreased to a great extent. A biopsy showed a definite prickle cell epithelioma in the tongue the past two weeks he has received two radium treatments, that is since this paper was read

The antiluetic treatment in the group studied consisted of arsphenamine, bismuth, and mercury

11 received arsphenamine (alone) 9 receiving 5, 1 receiving 8, 1 receiving 12

1 received 8 arsphenamine 6 received arsphe namine (6) mercury (3)

2 received about 5 each of arsphenamine, mercurv and bismuth

2 received bismuth alone, 2 received arsphena mine and bismuth

1 received 5 arsphenamine, then after operation 35 arsphenamine, 40 mercuries Died after second operation

Saturated solution of potassium iodide was also administered by mouth in water in gradually increasing doses starting on ten drops, mouth wash locally, analgesics for the prin

### Conclusion

You will all agree with me that arsphenamine has no effect on malignancy in the absence of If given where there is metastatic in volution of the liver the treatment for the accompanying syphilis may produce fatal results Again, in cases of malignancy developed upon an ante dated syphilitic as in gumma of the tongue, some authorities believe vigorous treatment for sylulis is imperative after operation or after radium treatment to prevent gumma recurring and perhaps new malignant degeneration

Although the medical world is spending freely of its energy time, and money and has made

much progress in the cancer problem, yet it is very difficult for us to think of anything but a tatal prognosis where the combination of progressive malignancy of the tongue is present in a syphilitic subject. The laity is now warned to avoid delay in consulting a physician and I believe this same call for prompt decision and action must be adhered to on the part of the Valuable time is only too frequently physician lost by endless waiting

The first task of the physician is to quickly decide whether to offer hope to this plighted in dividual in the field of surgery, radium or a ray A positive decision means an immediate action It may also be well to sterilize the patients with

one or two doses of arsphenamine

In case the patient weathers his initial experi ence, then one may follow with the lesser active antiluetic treatments as mixed preparation of potassium iodide and mercury, mercury rubs etc Arsenicals in very small doses may then be used Providing the patient is too far advanced for any attempted curative measures the use of antiluctics should likewise be omitted unless merely to fur nish a psychic relief

A certain percentage of patients may not give strong enough clinical evidence to make a ding nosis of carcinoma, little less advise operation of other active therapy, and it is in these cases that one is attempted to resort to more palliative mea sures such as antiluetic treatment. Here again we must school ourselves in the necessity of remembering the time factor My experience with these cases is to immediately perform a biopsy, and while waiting for the pithological report of tissue submitted, administer mild syphilis therapy Once the diagnosis is estab lished let us act with precision and speed

### A DEVICE TO CONTROL FECAL INCONTINENCE By ARTHUR A LANDSMAN MD, NEW YORK, N Y

LCAL INCONTINENCE is a disability which interferes seriously not only with a person's happiness but with his means of entning a livelihood One of my patients, a cigar maker, was compelled to give up his occupation because his fellow workers objected to itting ilongside of him on account of the unpleasant odor. A structural steel worker, whose job kept him many stories above the street in unfinished buildings had to give it up because of the annoyance caused by lack of control and absence of sanitary racilities close at hand. He was obliged to carry extra suits of underwear to be prepared for the emergency

The usual manner in which those so troubled protect themselves against soiling is by cirrying

a rubber cup and bag fastened to the body, to net as a receptacle for stools as they are discharged The cup and its fittings are cumbersome, uncomfortable in hot weather, and so un pleisant to handle at all times that they add no little to a patient's worry and mental depression But then main objection is that they may have to be emptied and cleansed it most mopportune times and places, that they can not be kept free from fecal odor and in time lead to excenations und infection of the skin around the stoma. At best they serve merely as a receptacle for the storage of feces, a type of badly smelling septic truk which the patient has to carry with him to his business and social engagements To overcome these objections a device is here

presented to prevent the expulsion of the stool and not merely dispose of it after it is discharged (see illustration). It is similar to the anal dressing tube described by Asman, which consists of a spool-shaped contrivance to permit the discharge of gases after rectal operations; but the present device differs from Asman's in that its ends are securely sealed to enable it to function as a plug and close the opening in the intestine.

The apparatus consists of a hollow soft rubber stem, one inch in circumference and one and three-quarters inches in length, mounted on an oval base, to one end of which is attached a single piece of rubber tubing of suitable length with a number of perforations one of which after a cleansing enema reinserted the next morning.

Many attempts have been made to secure mechanical control of incontinence by various means, all of which act on the principle of a cork in a bottle and are disappointments because there is nothing to prevent them from becoming displaced as soon as peristalsis and increased abdominal pressure signalize the onset of defecation. The plan described here differs from them because it depends on closure of the upper end of the canal by the extension of the stem and attempts at defecation only hold it more closely against the funnel-shaped distal portion of the passage. The apparatus is especially useful in

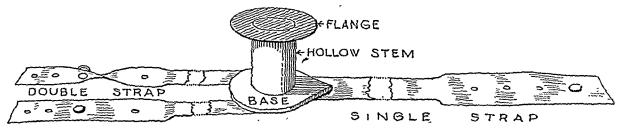

Diagram of Device for Controlling Fecal Incontinence.

The other end is rounded and holds a button. has two rubber straps similarly equipped. The portion of the stem opposite the base is closed by a circular rubber extension one-half inch wider than the end of the stem. The apparatus is greased and slipped into the bowel for a distance of one and one-half inches, when it opens up somewhat like an umbrella and sits at the lower level of the rectal ampulla as would a valve on the cylinder head of an automobile, thus closing the distal end of the canal. It is held in place by elastic suspenders buttoned behind and in front to keep it applied to the body. Gases may be allowed to escape by slight pressure on the anal end, which lifts the flange away from the upper part of the canal, but solid stool is retained in the ampulla. Should there be abdominal distress or a desire to defecate the patient will have ample time to visit a toilet. Otherwise the device is worn all day, removed at night, when a protective dressing may be put on and

cases where the incontinence is a symptom of Tabes, cerebro-spinal Syphilis, tumor of the lumbar cord and other conditions which may be complicated by relaxation of the sphincters and loss of tone of the perineal muscles, as these people, hecause of their disturbed sensations, are hardly aware that they carry a foreign body and soon become well accustomed to it. One of my patients has been using this since the last 5 years with satisfaction.

With suitable modifications the apparatus may be worn in cases of artificial anus for Carcinoma of the Rectum to do away with the Colostomy cup or close the stoma of an Ileostomy opening to check the dribbling of liquid stools and the disgusting odor which is such an annoying feature in these cases. It is well known that the usual form of Colostomy cup in time produces atrophy of the muscles around the opening and a ventral hernia which adds much to the patient's troubles and may be prevented by the wearing of this device.

### HAY FEVER: ITS DIAGNOSIS

### STUDIES IN HAY FEVER V.

By A. A. THOMMEN, M.D., NEW YORK, N. Y.
From the Allergy Clinic, University and Believue Hospital Medical College, New York University.

HERE are two aspects to the diagnosis of hay fever; namely, (A) the clinical or symptomatic diagnosis, and (B) the specific diagnosis.

cific diagnosis.

(A) The symptomatic diagnosis. In a previous paper the writer discussed in detail the various symptoms and signs of the hay fever syndrome. The clinical manifesations of the malady are divided into 1, the catharrhal symptoms, and 2, the asthmatic symptoms.

I. The catarrhal symptoms of hay fever are due to an inflammatory condition of those mucous membranes which are more readily accessible to the various wind borne pollens known to be the exciting cause of the malady. (The role of pollen in hay fever causation, and the other etiologic factors as well, has been dis-

cussed in a previous paper.2)

The symptoms are those of a more or less severe coryza—nasal congestion, rhinorrhoea, sneezing, mouth breathing, profuse lachrymation, photophobia, conjunctival irritation, oedema of the lids, and occasionally chemosis. The mucous membrane of the palate, uvula, fauces, naso-pharynx and eustachian tube are irritated and congested.

The outstanding features and characteristics of this particular coryza which aid in its recog-

nition are:

1. Itching and burning. These are very characteristic of the malady, and affect the mucous membranes of the eyes, nose, mouth and pharynx, and occasionally the skin of the face and neck. These sensations vary from trivial mildness to the most intense severity. They occur in paroxysms, determined by the concentration of atmospheric pollen, and the degree of clinical sensitivity.

2. Sneezing. The sneezing caused by hay fever is definitely paroxysmal; is rarely single, but occurs in groups or series of five, ten, twenty or more. Moreover, the threshold of excitability of the sneeze reflex is greatly lowered, so that it is readily stimulated by many otherwise innocuous causes, e.g., draughts,

dust, smoke, bright lights, etc.

3. Periodicity. Hay lever subjects can readily recall that they suffered in like manner at the same season of the year in previous years. There are three well-defined seasons: Spring hay fever, caused by the pollen of trees; Summer hay fever, in which the pollen of grass is the causative factor, and Autumnal hay fever, caused by weed pollen. (For a detailed discussion of the tree and grass type of hay fever the reader is referred to former studies. .\*.)

4. Duration. The malady (in the northern half of the United States), lasts more than five weeks (five to eight weeks), in the majority of instances—since the majority of hay fever subjects suffer from either grass pollen hay fever, which lasts from about June 1st to July 20th—or from weed pollen hay fever, which begins about August 15th and terminates about October 1st. In the case of tree pollen hay fever, the malady may last one to four or more weeks, depending on the particular tree or trees to which the patient is sensitive. In the southern states the individual seasons last much longer; in some instances six to nine months (particularly the grass type), owing to the longer period or multiple periods of pollination.

5. Heredity. The influence of heredity is strongly marked in hay fever. (For a fuller

discussion see 1.)

6. Variation of intensity. The symptoms of hay fever are definitely influenced by the various meteorological phenomena—amount of sunshine, rain, temperature, velocity and direction of the wind, humidity—insofar as these influence the quantity of pollen in the atmosphere; for example, hay fever subjects suffer less, or are completely relieved on rainy days, because the offending flowers fail to open, and the atmosphere is cleared of pollen. When conditions are such as to foster the shedding of pollen, as on bright, sunny, warm, more or less windy days, the symptoms are always intensified.

7. Termination. In many instances the symptoms terminate with surprising suddenness. Frequently, patients retire after a day of considerable suffering to awaken in the morning quite free from symptoms. It is often a matter of but a few hours between the condition of mucous membrane congestion, intense irritation, lachrymation, sneezing, etc., and more or less complete freedom from symp-

8. The absence of permanent pathologic changes. It is surprising that so many patients suffer severely from hay fever year after year, without the production of any permanent pathologic changes. If one were to observe for the first time a severe case of pollen conjunctivitis, which has lasted several weeks, with all the attendant symptoms, he would surely be warranted in predicting the production of some definite, marked, permanent pathology as a sequellum. Yet such is rarely the case. No doubt other abnormalities are frequently ag

gravated by hay fever, but it is doubtful whether they are ever thereby inaugurated. The writer is convinced, for example, that hay fever subjects are not more prone to polypoid degeneration of the nasal mucosa than individuals not pollen-sensitive.

II. Hay Asthma (pollen asthma). Pollen asthma in its symptomatology, does not differ from other asthmatic seizures of the hypersensitive type. Some of the characteristics enumerated above in relation to the catarrhal symptoms of hay fever, also apply to the asthmatic phase. As a rule, the diagnosis is readily made for it develops in the hay fever season, and in association with the catarrhal symptoms. There are instances, however, in which the catarrhal symptoms are so mild that they may be easily overlooked. Such instances are, however, not common.

Pollen asthma, unlike the catarrhal symptoms, does not always terminate at the end of the hay fever season, but frequently especially after several yearly recurrences, develops into perennial asthma, due, probably, to a complicating bacterial infection of the bronchial mucosa.

B. The specific diagnosis. It is a well established fact that in individuals who are subject to hay fever or hay asthma the skin, as well as the mucous membranes, is capable of a specific response to the particular pollen (or pollens) which produces the symptoms. It is this capacity of the skin to so react which is the basis of the specific diagnosis of hay fever. There are two methods of eliciting the specific skin reaction: 1, the intradermal method and 2, the scratch method.

1. In the intradermal method, a small quantity (0.02 c.c.) of sterile pollen extract is injected into the mesodermal layer of the skin, thereby producing a definite wheal quite in accord with the technique of the Schick test. A tuberculin syringe and a 26 or 27 gauge, % in needle is best suited to the purpose. If the patient is sensitive to the particular pollen tested, a positive reaction will occur at the site of the test; if the patient is not sensitive to that pollen, there will be no response—the wheal produced by the test injection does not increase in size and is soon resorbed.

Technique. The skin is held taut and the hypodermic needle introduced into the uppermost layer, with the barrel of the syringe held lower than the needle point. When the fluid is properly injected, a definitely circumscribed wheal results. A refinement of technique consists in the introduction of the needle (bevel upward), until one-half of the bevel enters the skin, when the needle is turned and the syringe barrel lowered, thereby pressing the outer half of the bevel against the skin.

The most convenient site is the outer aspect of the upper arm. Localized areas of inflammation caused by the individual tests may remain for 24 to 48 hours or longer, particularly if a number of marked reactions have been obtained. Occasionally such outward evidence of the testing process may be objectionable in which case the tests may be made on the thigh adjacent to the knee.

The tests, each an inch apart, may be arranged in rows of six. Care must be exercised not to make too many tests, or with too concentrated solutions, of those pollens which may give marked reactions, in order not to induce a constitutional reaction; e.g., it would be unwise to test a late hay fever case with more than three related pollens (of the ragweed group) in strengths of solutions giving marked reactions.

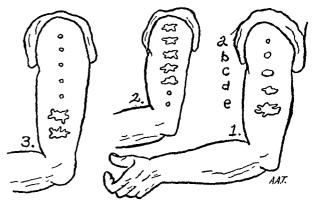

Figure 1. Skin reactions to pollen extracts.

The Reaction. Fig. 1 depicts the gradual development of a positive reaction; a. represents the test injection and b., c., d., and e. the various stages of development of the reaction—e. the final stage, indicating a marked positive re-Note the so-called pseudopods. should be stated that these progressive stages of development are here represented as occurring at different sites, for diagrammatic purposes; they of course occur at the site of the test When there is no positive reinjection a.) sponse, the test wheal remains as at a. or b. till. it is resorbed. Fig. 2 represents positive reactions to five different grass pollens and two negative reactions to high and low ragweed, respectively. Fig. 3 depicts negative reactions to five grass pollens, and two positive reactions to the two ragweeds.

The scratch test. This is performed by abraiding the skin with a fine scalpel, or other sharp instrument (e.g. a properly protected safety-razor blade). The abrasions are usually made on the upper surface of the forearm, about 1 inch apart; and one-eight in long, and never so deep as to draw blood. The pollen

solution is placed on the abrasion, so that it may be absorbed into the skin, and a reaction thereby produced, if the patient is sensitive to the pollen in question

The intradermal technique possesses several advantages over the scratch method 1 The latter is less certain, in that the pollen solution must be absorbed through the scratch, whereas in the intradermal method the test solution is definitely put in place ie, into the mesoder-The scratch method is mal laver of the skin known to give, occasionally, a negative response in individuals who are readily shown to be positive by the intradermal method With the intradermal technique a reaction develops in 3 to 7 minutes, with the scratch method a period of 15 to 20 minutes is often necessary 3 It is necessary that the arm be kept in a definite position so that the test solu tions will not flow off, in the scratch method This is frequently an irksome phase of the The chief disadvantage of the intradermal method is that it requires sterile solutions, which is minimized, however, by the fact that the same solutions are used in administering the treatment. The supposed disadvantages of its being too sensitive and of producing constitutional reactions are obviated by sufficient experience in the use of the method

The degree of reaction Reactions, when positive are recorded according to degree as slight, moderate, marked and marked plus Slight reactions are those which are but slightly greater in size than the original test wheal They have no significance unless produced by weak dilutions, in which instance they serve as indications to test with stronger solutions moderate reaction is usually about twice the size of the test wheal, is round in outline, surrounded by an area of erythema, and often accompanied by itching Reactions are marked when they show distinct pseudopod forma tions, besides producing the erythematous area and the sensation of itching A markedplus reaction is a marked reaction which is more than one inch in diameter

The significance of the skin reaction marked skin reaction almost always indicates that the patient is clinically sensitive to the pollen tested-that is to say, he will develop symptoms on adequate exposure There are, however, three well known exceptions to this rule, which must be borne in mind,

(1) Individuals who give positive skin reactions but who have not yet developed mucous membrane sensitivity Such instances are usu ally brought to light while skin tests are being made for some other form of hypersensitiveness, as asthma Such positive skin tests sigmfy that those patients are potential hay fever subjects

(2) Individuals who give both skin and eye reactions often to very dilute pollen solutions, but who do not develop hay fever, even though subject to an adequate exposure Such persons are also to be regarded as potential suffer ers, the mechanism of their protection, however, is unknown

(3) Patients in whom a clinical sympto matic cure has been brought about either spontaneously or as the result of active immunization, are usually found to have retained their skin sensitivity and their conjunctival

sensitivity as well

It should be evident from the above that it is always necessary to establish the clinical relationship of a positive test with the particular season in which the patient's symptoms oc-Because a patient gives positive reaccur tions to certain pollens does not warrant the conclusion that the patient has hay fever, caused by those particular pollens tests are to be viewed as clues the correctness

of which must be proved Preliminary tests Preliminary qualitative tests may be made to determine the pollen or pollens to which the patient is sensitive. The history of a given case determines the group of pollens which are to be tested, the pollens of the various trees are related to the spring type, the grasses and plantain to the summer type, and weed pollen to the late summer and fall type

After it has been deter-Quantitative tests mined by means of the history, or by the preliminary tests to which pollens a patient is sensitive, quantitative tests are made in order to determine the degree of sensitivity. The majority of hay fever subjects can be classified into four groups-Class A being the most sensitive, and Class D the least It has been determined that the amount of the excitant of hay fever present in a pollen extract parallels the amount of nitrogen present therein Test extracts are, therefore referred to as 0001. 001, 01, 05-meaning mgm of nitrogen per Class A

Class B

001 marked plus	001 marked 01 marked plus
Class C 001 moderate 01 marked	Class D 01 moderate 05 moderate or
	marked

In actual practice, tests are at first made with the 0001 and 001 strengths, after about 5 to 7 minutes have elapsed readings are made and it can then be determined whether it is necessary to make further tests

gravated by hay fever, but it is doubtful whether they are ever thereby inaugurated. The writer is convinced, for example, that hay fever subjects are not more prone to polypoid degeneration of the nasal mucosa than individuals not pollen-sensitive.

II. Hay Asthma (pollen asthma). Pollen asthma in its symptomatology, does not differ from other asthmatic seizures of the hypersensitive type. Some of the characteristics enumerated above in relation to the catarrhal symptoms of hay fever, also apply to the asthmatic phase. As a rule, the diagnosis is readily made for it develops in the hay fever season, and in association with the catarrhal symptoms. There are instances, however, in which the catarrhal symptoms are so mild that they may be easily overlooked. Such instances are, however, not common.

Pollen asthma, unlike the catarrhal symptoms, does not always terminate at the end of the hay fever season, but frequently especially after several yearly recurrences, develops into perennial asthma, due, probably, to a complicating bacterial infection of the bronchial mucosa.

B. The specific diagnosis. It is a well established fact that in individuals who are subject to hay fever or hay asthma the skin, as well as the mucous membranes, is capable of a specific response to the particular pollen (or pollens) which produces the symptoms. It is this capacity of the skin to so react which is the basis of the specific diagnosis of hay fever. There are two methods of eliciting the specific skin reaction: 1, the intradermal method and 2, the scratch method.

1. In the intradermal method, a small quantity (0.02 c.c.) of sterile pollen extract is injected into the mesodermal layer of the skin, thereby producing a definite wheal quite in accord with the technique of the Schick test. A tuberculin syringe and a 26 or 27 gauge, % in. needle is best suited to the purpose. If the patient is sensitive to the particular pollen tested, a positive reaction will occur at the site of the test; if the patient is not sensitive to that pollen, there will be no response—the wheal produced by the test injection does not increase in size and is soon resorbed.

Technique. The skin is held taut and the hypodermic needle introduced into the uppermost layer, with the barrel of the syringe held lower than the needle point. When the fluid is properly injected, a definitely circumscribed wheal results. A refinement of technique consists in the introduction of the needle (bevel upward), until one-half of the bevel enters the skin, when the needle is turned and the syringe barrel lowered, thereby pressing the outer half of the bevel against the skin.

The most convenient site is the outer aspect of the upper arm. Localized areas of inflammation caused by the individual tests may remain for 24 to 48 hours or longer, particularly if a number of marked reactions have been obtained. Occasionally such outward evidence of the testing process may be objectionable in which case the tests may be made on the thigh adjacent to the knee.

The tests, each an inch apart, may be arranged in rows of six. Care must be exercised not to make too many tests, or with too concentrated solutions, of those pollens which may give marked reactions, in order not to induce a constitutional reaction; e.g., it would be unwise to test a late hay fever case with more than three related pollens (of the ragweed group) in strengths of solutions giving marked reactions.

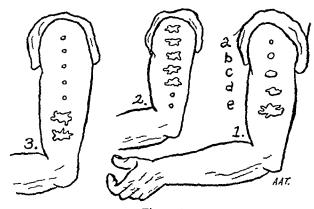

Figure 1. Skin reactions to pollen extracts.

The Reaction. Fig. 1 depicts the gradual development of a positive reaction; a. represents the test injection and b., c., d., and e. the various stages of development of the reaction—e. the final stage, indicating a marked positive reaction. Note the so-called pseudopods. should be stated that these progressive stages of development are here represented as occurring at different sites, for diagrammatic purposes; they of course occur at the site of the test injection a.) When there is no positive response, the test wheal remains as at a. or b. till it is resorbed. Fig. 2 represents positive reactions to five different grass pollens and two negative reactions to high and low ragweed, respectively. Fig. 3 depicts negative reactions to five grass pollens, and two positive reactions to the two ragweeds.

The scratch test. This is performed by abraiding the skin with a fine scalpel, or other sharp instrument (e.g. a properly protected safety-razor blade). The abrasions are usually made on the upper surface of the forearm, about 1 inch apart; and one-eight in long, and never so deep as to draw blood. The pollen

pause.

(2) it continues long after the latest known form of hay fever, occurring in the warm weather of late November or early December; (3) unlike hay fever, there are no definite periods of intermission, but periods of remission (during cool days); (4) the symptoms are confined to the eyes; (5) in contrast to hay fever. there develops a definite permanent pathology consisting of conjunctival, papillary growths which resemble a payement of cobblestones; (6) skin tests with pollen extracts, etc., are negative.

### LOW VOLTAGE X-RAY FOR A THERAPEUTIC MENOPAUSE By I. CRAIG POTTER, M.D., ROCHESTER, N. Y.

 $\mathbf{T}^{ ext{HE}}$  purpose of this article is to recall the fact that low kilo-voltage may be satisfactorily used in the production of a therapeutic menopause. In the early days about a seven inch point gap was the limit for the gas tube and pioneer equipment; yet over one thousand benign gynecological conditions (4), mainly small fibroids and functional bleeding cases, were reported cured by it. The experience of the following years has confirmed the advantages of the x-ray treatment of menorrhagia.

The introduction of the Coolidge (2) tube in 1914 made possible the use of one hundred kilovolts, or a nine and one-half inch gap, which then constituted "deep x-ray therapy" (1). With the development of more powerful machines low voltage therapy was neglected. Hanks (3), however, is still using successfully low voltage (100 to 120 kilovolts) to produce an artificial meno-

treatments, or an average of three treatments, to produce a menopause. Two of these fifteen treatments were followed by nausea and vomiting, as shown by a circle on the chart; otherwise there was little reaction outside of an exhausted feeling and loss of appetite. Luminal, light diet, rest the first twelve hours, and dividing the treatment definitely decreases x-ray sickness.

Flashes have been severe in only one patient. In general there has been less nervousness since the menopause than during the preceding ill health, while one patient with periodic headaches has been practically free from them. There have been no skin changes. The blood counts have all returned to normal. The greatest gain in weight has been sixteen pounds, the average three and one-fifth, not more than one would expect from the improvement in the patients' general condi-In all cases the uterus has returned to practically normal size.

### ECONOMICS

The following resolution was introduced in the House of Delegates on June 2, 1930:

"Resolved, that the New York State Journal of Medicine devote more space to economic matters in reference to scientific articles."

The Reference Committee reported:

"We recommend that this resolution be re-

ferred to the Editor-In-Chief of the Journal." This suggestion was adopted by the House.

The extension of hospital facilities is an economic procedure of great importance to physicians as well as to the people. Turn to page 925 and read what the physicians of England are proposing,

### THE PRESIDENT'S COMMENTS ON CURRENT ACTIVITIES NO. 3

The July eighth meeting of the Oneida County Medical Society was addressed by Dr. O. W. H. Mitchell on "County Health Departments" and by Dr. W. H. Ross on "The Need of Modernizing Medical Relationships." An interesting part of the discussion was on the proper solution of the problem of relationship of the urban part to the rural part of a county in a county health department. The law at present permits a city by vote of its Council to become a part of the county health department. This unity of organization is desirable, but presents at present apparent difficulties that will require considerable thought for solution.

The Wyoming County hospital organization was practically completed on July eleventh when a public meeting of the Board of Supervisors, the County Medical Society, and many interested citizens of the county was addressed by the State Commissioner of Health who approved of state aid of forty thousand dollars which amount represents one-half of the cost of purchase by the county of the Wyoming County Community Hospital, and by Dr. William H. Ross who discussed the essential relationship of a County Medical Society a State aided County Hospital staff. Dr. Parran stated the following conditions under which he would approve, in principle, state aid yearly to the extent of one-half of the hospital's yearly deficit incurred in giving medical care to the people of the county who could not pay for it.

1. That the hospital be operated and main-

tained in accordance with law.

2. That the professional standards in the hospital continue to meet the minimum requirements established by the American College of Surgeons for an approved hospital.

3. That any licensed physician in the county be entitled to send patients to the Hospital, and to give such patients general medical and obstetrical care therein, subject to such regulations as may be prescribed by the hospital board of managers and approved by the State Commissioner of Health.

4. That the Board of Managers of the Hospital appoint a medical board chosen from a list submitted by the County Medical Society, such medical board to recommend for appointment physicians qualified in the several medical and surgical specialties to the attending and consulting staff of the hospital and to recommend, subject to the approval of the State Commission of Health, proper standards for professional service in the hospital.

Dr. Ross discussed the teaching value of a

hospital and its influence in raising the standards of medical practice in the community.

The second meeting of the Special Health Commission was held in the Executive Chamber in Albany on July fourteenth. Governor Roosevelt called the meeting to order In addition to the members of the Committee Dr Frederick W. Parsons, State Commissioner of Mental Hygiene, Dr. Charles H. Johnson, Director of the State Department of Social Welfare, Mr. Berne A. Pyrke, State Commissioner of Agriculture and Markets, Dr. Henry F. Mace of the Department of Education, and Dr. Robert S. Birney of the Department of Labor were present. The several State Departments dealing with problems closely connected with public health were, therefore, represented at this meeting of the Commission.

In opening the conference Governor Roosevelt announced the appointment of a commission to direct the development of Saratoga Springs as a health resort.

During this conference it appeared that the question of future school and medical and health work was probably the knotiest one the Commission would face. A proposal to enlarge the personnel and functions of the Public Health Council to include representatives of state departments concerned with health problems commanded attention. Governor Roosevelt felt that there was a changing relationship between state and local authorities and he felt that the health burden should be put on the locality with the state serving only as an inspecting force with power to see that health work was done according to accepted standards but Commissioner Pyrke pointed out that the wealth of the state was not equally distributed and that the state was the greater equalizing agent by allowing help to the poorer counties.

The need for a definite state policy to prevent running wild with the present very broad laws in health matters as to State aid was discussed. More than twenty special topics are being studied by the Commission, each one under a chairman who has been given power to invite others to assist in the study. This has been done to the extent that now more than sixty people with wide distribution of knowledge in widely separated sections are working on the various problems presented. Governor Roosevelt stressed the importance of more county health departments for the better administration of public health.

WILLIAM H. Ross, M.D.

### THE CHIDREN'S HOUR

The Department of Health of New York City is promoting the practice of preventive medicine by family physicians, and has developed a plan called the "Children's Hour," which is described in the July issue of Medical Economics in an article by Health Commissioner, Dr. Shirley W. Wynne. The plan is that each general practitioner of medicine shall set aside an hour during which he will receive children who are presumably well, and will administer antitoxins and vaccines, and give their parents hygienic advice on keeping the children well. The success of the plan will depend on giving publicity both among the doctors and the people. Doctor Wynne offers the services of the Health Department as the "advertising agent for the private practitioner."

Doctor Wynne makes four proposals for carrying out the plan:

- 1. A letter from the Department to every physician practicing in Greater New York, inviting him to set aside one hour in each week for children at a specified fee. Doctor Wynne expects a favorable response from at least four thousand physicians, or one third of those practicing in New York.
- 2. Doctor Wynne will provide each physician with letters, bearing the imprint of the Department of Health, which the physician will send to his families, stating the office hour and the fee for consultation.
- 3. Each doctor will also be provided with a card announcing his "children's hour" and the fee. This card is to be sent to the Department of Health and also to the County Medical Society, if the Society desires it.

4. Every doctor who accepts the plan will receive a display card for his office reading:

"I am asked by the Commisioner of Health to set aside a 'Children's Hour' on ...... of each week at ...... when I shall see and examine well children, advise as to their feeding, general care and hygiene and give vaccinations, diphtheria protection and similar other treatment for keeping them in good health. Please bring your child to me so that I can help to protect the youngster's good health and so carry out the wishes of the Health Department.

Doctor Wynne closes with these paragraphs:

"The suggested letter, notice, record card and waiting room card constitute, in brief, our plan. It will at once be clear that this would serve as collective advertising, sponsored by the Department of Health, for the commendable purpose of raising the health standard of our pre-school child. Under modern conditions of life this form of advertising is not only legitimate but necessary.

"It would do what the private physician individually cannot do—invite his patients to come to him for medical advice on keeping well.

"It would enable parents to know that preventive medicine is available to them for a reasonable fee.

"It would stimulate the desire of parents to pay attention to the importance of keeping their children well.

"It would take the person of moderate means away from the free facilities."

### LOOKING BACKWARD

## This Journal Twenty-Five Years Ago

Medical Interviews: This Journal of August. 1905, discussed medical interviews editorially under the heading "Newspaper Doctors." Quoting the Globe and Commercial Advertiser of July 19, the editorial said:

"The practice of quoting as authoritative the opinions of unknown and hitherto unheard of physicians, which is unfortunately prevalent in certain newspapers, is reprehensible, not only because it readily degenerates into personal advertising, but even more, because it may deceive the lay reader into believing that Dr. So-and-So is qualified to speak with authority. There are a number of physicians in this city whose word on medical and sanitary subjects would frequently be of great immediate value to the public, but owing to their fear of getting the reputation of 'newspaper

doctors,' as one of them put it, they refuse to talk publicly on any medical subject. For many people the newspaper is the chief source of information on serious subjects, and the information which newspapers cannot get the public does not get."

This Journal then makes the following suggestion which the Medical Societies of the counties of Kings, and New York are now trying to carry out:

"The best solution of this question, thus far offered, is the appointment of a committee by the local medical society, which will hold itself ever ready to grant interviews and to give voluntary information on anything of public interest which involves professional opinions."

## **MEDICAL PROGRESS**

Malarial Treatment of Multiple Sclerosis .-G. L. Dreyfus and K. Mayer conclude a serial on this subject with the following remarks. The research had been carried out for five years and covered 40 cases. The treatment is not dangerous if we exclude groups of cases in which it is for-The latter comprise mally contraindicated. patients who are in bad physical condition and those who suffer notably from affections of metabolism and the circulation. In all doubtful cases the malaria treatment should be preceded by treatment with glucose-strophanthin. there be present cases with high degrees of deficiency symptoms of the brain and cord the malarial treatment should be excluded, even if the case is recent, nor is it permissible in long standing cases. The best prognosis for the success of the treatment is given by the recent case and even as early as the third year the chance of a good result is less favorable; and the best age period is from 18 to 40. No difference exists in the prognosis between the constant and the relapsing case and there is no difference in sex. Judging by the authors' experience, when dealing with properly selected cases the percentage of permanent cures should lie between 30 and 40. Further experience will be required to determine the possible addition of synergists to malarial therapy, as the use of other fever-producing substances, combination with salvarsan and antimonial substances, etc. Thus a course of malaria treatment could be succeeded by antimony or arsenic in organic form, and this in turn by a course of recurrent fever infection. The foreign protein substances might also be interposed in a course of treatment, while gold and bismuth salts may have value.-Deutsche medizinische Wochenschrift, May 23, 1930.

Three Fatal Cases of Nasal Sinus Disease.—
Prof. W. Uffenorde relates a case of fatal sepsis
with combined unilateral nasal sinus disease. The
patient was a strong young girl with a recent
history of simple angina followed by a severe
cold. Examination showed involvement of the
left antrum and frontal sinus. Operative drainage brought no relief and symptoms of sepsis
developed. The blood was sterile. Death followed
shortly without apparent cause. Autopsy showed
the encephalon intact, as was the right side
of the nose. The heart, kidneys, and liver showed
evidences of septic lesion, but the exact mechanism
of death was obscure. A second case is briefly
outlined. It occurred in a woman of 44 who
died in a week following neuralgic pains about

the head and face, chills, and vomiting. Autopsy showed an acute sphenoidal sinusitis, thrombosis of the left cavernous (venous) sinus, and meningitis, with metastases in the lungs and pleura. Evidences of sepsis were apparent. In a third case a girl of 20 first developed apparent influenza, followed by headache, prostration, sweating, chills, and a convulsion. Suspicion of puerperal eclampsia was shown to be unfounded. The convulsive seizures continued and the author had motion pictures of them taken. The attacks succeeded one another rapidly and after the 30th the patient sank into a fatal coma. Autopsy revealed purulent meningitis secondary to right-sided frontal sinusitis. Sepsis is not mentioned. Several other cases are quoted from the practice of the author and others, enough to show the menace of sinus infection.—Deutsche medizinische Wochenschrift, May 9, 1930.

Epidemiology of Cerebrospinal Meningitis .--Dr. H. Kapp of Basle states that during a considerable epidemic, as that in Germany from 1905-7, we can understand fairly well the means of diffusion, but conditions differ widely on more sporadic incidence, for we have to consider germ carriers and cases of pharyngitis. We have learned that the disease is essentially a specific pharyngitis and that penetration of the coccus into the cerebro-spinal canal is a secondary manifestation, a mere complication. It is not difficult to understand how heightened virulence or lowered resistance can produce an epidemic of meningitis, but sporadic cases of the latter are much more difficult to understand. The author describes three cases of the latter in which there was at first little or no clinical suggestion of meningitis. The diagnosis was made by lumbar puncture. All were adults and soldiers. There was a history of exposure, past and indirect, and of angina. They had probably been carriers for the time being. The cocci usually persist in the throats of carriers for a short time only-say a month, but exceptionally there is a persistence for much longer periods. Carriers have been believed immune to the disease but sometimes they fall victims to it .- Schweizerische medizinische Wochenschrift, April 20, 1930.

Primary Lesions of Rheumatism.—Prof. S. Graff of Hamburg has sought for years the primary lesion of ordinary rheumatism, from which the organism at large may be infected, not only once but at times repeatedly. The existence of a specific granuloma has already been postulated, but this is not necessarily a primary manifesta-

The author has sought the latter in the tonsil and has been able to distinguish between primary and secondary manifestations by histological technique. In a case of acute polyarthritis ending fatally in 16 days, he was able to study the tonsils and found a peculiar focus which appeared to extend through the peritonsillar muscular tissues, and he termed the entire lesion the primary complex. Metastases to the joints and heart are believed to take place through the venules of the complex. Tonsillar lesions are not all primary, for in the present case the opposite tonsil was of a different type of lesion, regarded as metastatic. Histologically, there was marked resemblance to the primary lesion, but in appearance it was much younger. The author does not discuss the possibility of a superinfection from without. In other fatal case the tonsillar structure suggested that the primary lesion may undergo changes with age, due probably to superinfection. This patient had undergone two severe episodes of general infection. The author made no bacteriological studies, and it is immaterial to him whether the disease is due to a streptococcus or some other organism. He is concerned with the histological reaction alone. Neither does he touch on latent infection in the tonsil as a source of lesions of the focal infection type.—Deutsche medizinische Wochenshrift, April 11, 1930.

Some Principles in the Modern Treatment of Rheumatic Disease.—W. S. C. Copeman states that the multiplicity of agents employed in the treatment of rheumatic disease does not indicate failure to find a suitable remedy, since it appears more and more obvious that the intelligent combination of remedies is the keystone to success, the danger lying in the adoption of any one method, to the exclusion of the rest. preliminary treatment in both arthritic and nonarthritic types of the disease should be directed toward eliminating foci of infection, paying special attention to the colon. As most persons with rheumatoid arthritis have been forbidden to eat meat, they come to depend upon carbohydrates which encourage the fermentative and putrefac-They should be persuaded back to tive bacteria. the paths of protein, fat, and adequate vitamins (especially vitamin B). The most-efficient forms of local treatment are hydrological and physical, particularly if sweating can be induced. Rest, avoidance of cold and constipation, with a diet well balanced in chemical and vitamin content. are most important. In osteoarthritis, a disease of advancing years, an effort should be made to promote elimination of those products of metabolism which tend to be retained at this time of life more than previously, and for this reason spa treatment is of great benefit. In this type of arthritis local treatment is mostly directed toward relieving pain and improving the functions of the skin and muscles by hydrotherapy and massage, and later electrotherapy. Increase of body weight should be avoided. In the treatment of rheumatic disease vaccine therapy has been disappointing. The results of non-protein therapy tend to be of a temporary nature. Among useful drugs is iodine administered in milk; colloidal iodine and the ordinary tincture seem ineffective. The salicylates have declined in popularity. Recently ortho-iodoxybenzoic acid and neocinophen have been much lauded. Arsenic is chiefly indicated in the atrophic type and in patients with anemia; it should be given in small doses, gradually increased, over long periods. Sodium cacodylate (1/4 to 1/2 grain) is probably the most harmless. In rheumatism the basal metabolism tends to be somewhat below normal; this suggests thyroid extract and its use is indicated particularly in climacteric osteoarthritis. Sulphur is believed by some to be of value.— British Medical Journal, May 24, 1930, i, 3620.

The Curability of Cancer.—John B. Deaver states that the curability of cancer depends upon early detection, early treatment, site of the tumor, its nature, presence or absence of metastases, and finally on the constitutional peculiarity of the individual concerned. order to emphasize the brighter aspect of the usually dark picture of carcinoma, he cites instances of cancer of the stomach and breast in which the patients are living and well six and eight years after operation, and of cancer of the fundus of the uterus in which the patients were alive and in good health twelve and twenty years after panhysterectomy. Present methods of treatment are, however, inadequate. The only cures have come from surgery with a few from irradiation. Newer knowledge and newer methods must be discovered. In the Research Institute of the Lankenau Clinic, under the direction of Stanley P. Reimann and Frederick S. Hammett, a study has been made of cell mitosis, because the one and only factor common to all kinds of cancer is cell division. It has been discovered that in the roots of plants and in animals, sulphur is present in the nuclei of cells in mitosis and that the sulphur must be present in a certain form combined with hydrogen, namely sulphydryl. If this is true, cells should divide and grow if given sulphydryl. It has been demonstrated practically in a number of stubborn wounds, such as leg ulcer and bed sores, that rapid healing was stimulated by the use of sulphydryl compounds. experiments justify the unequivocal statement that normal cell division takes place because sulphydryl is formed, and never takes place unless it is present. The next step is to find

the substance that stops cell division. That there is such an antidote is perfectly apparent. Otherwise wounds would never stop healing and children would never stop growing. There is here a chemical study of the first magnitude ahead of us. The kind of research which at present promises the best hope is the chemistry of the body which normally starts, stops, and controls cell division. Deaver emphasizes the importance of research work and urges intelligent philanthropists to provide endowment funds.—Annals of Surgery, June, 1930, xci, 6.

The Chemist's Concept of Cancer.-Robert A. Armstrong states that the chemist looks at the cancerous condition solely as one of chemicalization and from no other source than the blood stream may he obtain definite knowledge of its origin, and only from this source may he hope to find relief and correction. The great majority of malignant tumors are associated throughout their course with progressive deterioration in the quality and quantity of blood. Usually this is expressed in a loss of hemoglobin and an increase of leucocytes. In certain degenerative tumor cells, there is found a wide variety of alterations due to chemical action on the normal protein. Demineralization occurs in cancer cachexia in the later stages and is associated with nitrogen loss, and the calcium deposits become greatly disturbed, extensive deposits being frequently found in the tumor. There are changes in the colloids of the blood and in the electrolytes, which are extremely sensitive regulators of the colloidal state, and also in the catalytic agents. At least three elements in the blood are out of their normal accord, namely, sulphur, phosphorus, The oxycatalyst treatment of and nitrogen. cancer is founded upon the evidence presented in cancer cases, viz., (1) There is a chemical imbalance set up in the blood stream manifesting itself primarily as an increased alkalinity; (2) the cleavage of a normal protein in alkaline solution follows closely the stages of breakdown observed in a cancer mass, and the chemical results found in the blood confirm these evidences of breakdown which are proteoses, peptones, peptides, urea, ammonia, carbon dioxide, hydrogen sulphide, amino acid, and nitric oxide. The cancer growth is an electronegative mass and this condition is corrected by the introduction of an electropositive agency, which is the alpha particle of radium. This oxycatalyst, in addition to being radioactive and electropositive, is a constructive stimulating supplier of oxygen and through normalization of the blood stream and stimulation of the endocrine glands restores the potassium, sodium, and calcium metabolism. The efficacy of the treatment has been evidenced in a reasonable percentage of cases by the apparent removal of all the symptoms.— Physical Therapeutics, June, 1930, xlviii, 6.

Paget's Cancer to Date-L. Frankenthal. a surgeon of Leipzig, states the modern attitude toward Paget's cancer of the nipple. This is the only form of mammary cancer which may be difficult of diagnosis and of early recognition. A case is cited in a woman of 51 in which the lesion for weeks was a slight weeping surface hardly larger than a pin head with no apparent tendency to increase in size. Some months later a distinguished dermatologist examined the woman, but failed to recognize the nature of the lesion. Aside from the nipple lesion, the patient was perfectly well and vigorous. The author made a biopsy of sweeping dimensions and the diagnosis was carcinoma solidum plano-cellulare extending ininto the fatty submammillary tissue. A radical operation soon followed. Since 1874, when Paget published the first cases, a large amount of material has been studied and it now appears that something more than a unit disease is concerned. The malignant process may originate in the canaliculi or in the parenchyma of the gland. That the two types give a common histological picture can be explained by local peculiarities. Clinically the most constant manifestation is the eczematoid and itching alteration of the skin of the nipple. Even at this late date, but 140 cases of the affection are on record and less than 1 percent of breast cancer is diagnosed as of the Paget type. In many cases diagnosis is easy, but in others, as already stated, impossible without a biopsy. No partial operation is to be performed, but the entire breast should be excised and the axilla cleaned out. This gives the patient her only hope, for this type irradiation has been of no benefit. - Deutsche medizinische Wochenschrift, May 30, 1930.

The 1930 Type of Polyneuritis .- Benjamin T. Burley, writing in the New England Journal of Medicine, June 12, 1930, describes a new symptom complex as presented in 55 cases that have come under observation in the Worcester City Hospital since early in April. The general evidence given by the patients indicates that the paralysis usually followed, in from two days to two weeks or more, the ingestion of one or more two-ounce bottles of a fluid marked Jamaica Ginger. The onset was occasionally marked by mild gastric disturbance, but usually the first change noted was a peculiar paresthesia of the legs, a sense of coldness, tingling, and muscle fatigue in either the calf or the anterior aspect of the lower leg was followed in about a day by motor paralysis of the anterior tibial group in both legs, by toe-drop and marked ataxia. After about a week paralysis involved the hands and wrists, the intrinsic muscles of the hands and the extensor muscles of the forearm being particularly affected. Mottling, cyanosis, and a lowered local temperature usually occurred. Sensory changes were characteristically absent. The electrical reaction of degeneration was definite in all severe cases. Tenderness to deep pressure over the calf muscles was frequent in the second and third week of the paralysis, but there was no objective paresthesia as in alcoholic neuritis. The Achilles and plantar reflexes were lost; there was increased mechanical irritability in the paralyzed muscles, and atrophy gradually occurred. In general the rest of the body, except the limbs, escaped the lasting effects of the poison. Laboratory tests were made as to the white and red blood count, hemoglobin, Schilling differential count, sedimentation rate, Wassermann, Hinton, and Kahn reactions. There were no characteristic findings. As the affection is not detected until paralysis occurs, treatment resolves itself into a matter of after-care. The affected muscles are splinted in a favorable position, and later massage and the galvanic current are employed. The syndrome here described can be readily differentiated from other types of polyneuritis. The action of the toxic agent is evidently clinically identical all over the country according to the reports of many scattered cases.

Nature of the Pains of Muscular Rheumatism.—F. Lindstedt, of Stockholm seeks an explanation of the myalgic pains which characterize so-called muscular rheumatism. When these are present one should first seek to exclude neuralgia and also note carefully whether any other symptoms are added to the picture. Local causal agencies should be sought, as ordinary fatigue from overaction of certain muscles, and reflex factors must not be overlooked. Thus affections of the toes may make themselves felt in the lumbar or gluteal region as part of a fatigue syndrome. In polymyalgia, it may not be necessary to seek a general causal factor, for myalgia is often associated with radiating pains and it is possible at times to trace an extensive polymyalgia to overstrain of a single muscle group. The author's material is limited to about 800 dispensary cases, many of which would be classed as neuralgias because of their localization and absence of any obvious muscular overstrain. General causal factors appear to act upon this substratum through the element of exhaustion, which need not come from muscle overfunctioning. Psychic influences, anemia, and possibly toxic substances may cause a general exhaustion which is favorable for the development of muscle pains. Meteorological influences may also aggravate the latter. In summary the author states that so-called muscular rheumatism consists of painful sensations which are more or less of neuralgic nature, but the basic causal factor is muscular exhaustion which may have a varied origin. We should always visualize these myalgias as symptoms, never as an autonomous disease. They are not an essential part of gout or rheumatism but are due to the same causes and hence often associated with these disease entities. A more or less considerable rise of temperature, which is not infrequently encountered, does not necessarily indicate an infection.—Klinische Wochenschrift, May 31, 1930.

Phlegmon of the Floor of the Mouth.—Dr. Wassmund, director of the jaw clinic of the Rudolph Virchow Hospital, Berlin, treats of other conditions than simply those known as Ludwig's angina. The mortality of the latter is very high-something like 40 percent-and at the author's clinic an effort is being made to cut this figure down. Naturally phlegmonous must be separated from merely suppurative cases. The grippe of 1927 and 1928 left a large number of both types as sequels and thus far it has been impossible to determine the factors which cause the phlegmonous type. The totals for the two-year period mentioned are 72 cases of simple abscess without mortality, in 1927 and 71 without mortality in 1928; and 21 cases of phlegmon in 1927 and 14 in 1928, the mortality for the 35 cases being 4, or about 12 per cent, which is a great improvement over the average. For reasons unknown the dental infection which causes suppuration in the floor of the mouth and is usually a matter of diffusion by the lymphatics, may pass directly the submucous connective tissue and The gangrenous proccause a phlegmon. ess is apt to be active in the recesses which contain the submaxillary and sublingual glands but the author has never seen death result if it is limited to these regions. Death has invariably been determined by further extension of the process down the neck and mediastinum or upwards to the retropharynx, recess of the parotid, temporal region, intracranial cavity, etc. The author offers in explanation of his low mortality percentage the fact that his invariable custom has been to institute measures in anticipation of these extensions upward and downward. He has published a monograph in which the subject is exhaustively considered with many case histories.-Münchener medizinische Wochenschrift, May 23, 1930.

#### A DOCTOR'S CERTIFICATE

By Lorenz J. Brosnan, Esq. Counsel, Medical Society of the State of New York

Doctor, when you are called upon to sign your name to a certificate or other paper dealing with the physical condition of a patient or the physical disability resulting from the illness of a patient, be sure that the paper you sign is in all respects accurate. Before you put your name to any paper, make sure that you could support the contents of that paper under the most searching cross-examination to which you might be subjected in a court of

justice or elsewhere.

We venture to say that nearly every practitioner has at some time in his practice been requested by a patient to affix his name to some document regarding the patient's condition, to the contents of which the doctor cannot conscientiously subscribe. Instances of this kind frequently happen in relation to claims by patients under accident and health policies, and also in cases where the patient is entitled to compensation by reason of an accident arising in the course of his employment. It is important to remember that neither a desire to be kind to the patient nor any other claimed expediency will excuse the physician who certifies to something which he knows, or should know, is not accurate. When you give a patient a certificate to the effect that because of some physical ailment he is unfit for jury duty, remember that the judge to whom such certificate is presented may order you to appear before him forthwith to be examined with respect to the contents of your certificate.

A physician has written a splendid article on the general topic of a doctor's certificate. It appeared in "The Lancet," a journal of British and foreign medicine and bears the title, "On Signing Your Name." The author. Dr. Layton, is a well-known throat and ear surgeon of London

The author points out that the General Medical Council in England has issued a warning notice to the profession which contains, among

other things, the following.

"Registered medical practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates, notifications, reports, and other documents of a kindred character signed by them in their professional capacity,

for subsequent use either in Courts of Justice or for administrative purposes. \* \* \* Anv registered practitioner who shall be shown to have signed or given under his name and authority any such certificate, notification, report, or document of a kindred character, which is untrue, misleading, or improper, whether relating to the several matters above specified or otherwise, is liable to have his name erased from the Medical Register."

When patients seek to persuade you against your better judgment by an appeal to your sympathy, consider this very pertinent para-

graph from Dr. Layton's article.

"There is another very common reason given for asking a doctor to sign a certificate wrongly. It is that unless he does so, some poor person cannot draw the weekly money and the invalid, his wife and child must go starving without it. Against such suggestion you must rigidly set your face. Either the regulations for drawing the money are bad and should be amended, or the person bringing the certificate for signature has let time slip by, so that he or she is faced with the difficulty out of which you are asked to get him. In neither case is there any reason why you should put your signature to a false statement and risk the whole of your career thereby. Let there be no doubt about this. When you are faced with that document and its misstatement no arguments about doing it out of kindness to the sick will protect you. The case is bound to go against you and no one can save you."

Typical instances confronting an English physician are set forth in the following two cases related by the author:

"Case 3.—One evening a neighbor dropped in upon a doctor, asking him to sign a passport paper for her brother-in-law. He replied that he would be delighted but, on looking at the document, added that he could not, as it stated that he knew the applicant person-The lady indignantly suggested that surely he could trust her, adding that if he did not sign they could not go on their trip, as the paper must go in next morning and there was no time to get any other eligible person to sign. The doctor's wife supported her, not wishing to have any unpleasantness in a new

neighborhood to which they had recently moved."

"Case 4.—A doctor working at the Ministry of Pensions was asked by the head clerk to sign his paper for a weekly pension. He looked at it, and pointed out that the signature involved his saying he had that day seen the pensioner's children alive. In an unpleasant tone the clerk said, 'The children are at school, I can't bring them here.' The doctor suggested that he could during 12:30 and 2, and offered to wait during that period to see them. In a huff the clerk removed the paper, saying, 'I can easily get someone else to sign it. I have never been asked to bring the children before.'"

Dr. Layton has some interesting comments to make with regard to the signing of forms in blank and leaving someone else to fill them in. He cites an instance where, sometime ago, a nurse in a ward of a hospital to which she was attached asked the house surgeon to leave her some certificates, and the latter signed in blank some half dozen forms that the nurse had ready for him. Dr. Layton was amazed at this, and spoke severly of this to both the nurse and the house surgeon. The nurse argued that the house surgeon was out during the visiting hours when the relatives asked for the certificates, and that they would have to come again to the hospital if these were not ready. It was pointed out to the nurse that, with a little forethought on her part, the certificates could be gotten ready for the house surgeon to sign on his morning round. this the nurse responded that she could be trusted to fill them in properly. Characterizing this argument, the author says:

"This is a most dreadful argument to put forward. It is so difficult for a young man to controvert, especially when morning and evening he has to go round with the woman who puts it forward. The answer, of course, is that to sign a blank certificate is the same as signing a blank cheque for that, in effect, is what it is, the only difference being that it is a cheque on someone else's money. A house surgeon who gave the sister of his ward half a dozen blank cheques would be looked upon as a fool, but it is only his own money that can be drawn on them; to do so with documents on which someone can draw another person's money does not far remove

him from being a knave."

Dr. Layton has some interesting comments to make with respect to the consequences of a physician aiding and abetting a patient in his desire to take undue advantage of a sickness or accident insurance policy:

"To allow people unduly to remain away from work is bad medicine; when we have been ill we all need a little stimulation to return, and we never get quite fit until we do. The kindly encouragement of the general practitioner with his pat on the shoulder and his quiet-spoken 'Well, try for a day or so and see how you get on' must have enabled millions to resume work and to find to their surprise that they were ready for it. As our methods of practice pass into new shapes we want to retain this personal touch; and if we do not other methods must be found to supply that stimulus. To my mind the most serious point in these figures is that the increase is most marked among the young.

Let a layman put this medical view before you—again I quote Sir Walter Kinnear.

'The effort to resume a normal life is hard to make, no doubt, when the will is enfeebled by long incapacity and the introspection it induces. But the effort itself is invigorating, and, to a certain type, no greater service can be rendered than the exercise of gentle pressure to "try" which is expressed in the refusal of further benefit on the advice of an official medical referee.'

Remember that every time you knock a person off work unnecessarily, and every time you refrain from stimulating him or her to return when fit you are helping to manufacture a valetudinarian, and every time you allow a person to step into this you are on the way to making an unemployable."

Your counsel is in a position to state from personal knowledge that doctors are honest, conscientious men devoting their lives and their talents to the great healing art. Perhaps no one is in a better position than your counsel to see how often the doctor is misunderstood and how often he is unjustly criticized. Each individual physician has not only his own honor to uphold in the practice of his profession, but the honor of the profession as well. We commend most heartily the code of honor set forth by Dr. Layton with respect to the subject-matter of this editorial, when he says:

"As members of the medical profession we often have to sign our names to documents which appear at first to be of small importance but which may under certain circumstances have far-reaching effects. These documents fall under two heads, those which are signed by us as a part of our medical work and which contain some professional opinion, and those which we sign because the right or privilege has been given to us by the nation or otherwise as a mark of the confidence in which we are held. This power to sign our name should be held by us to be a sacred duty that we should at all times carry out with all the care that is within our power, \* \* \*."

# **NEWS NOTES**

#### HOSPITAL POLICY OF THE BRITISH MEDICAL ASSOCIATION

The supplement to the British Medical Journal of April 19, 1930, contains the report of the Hospital Policy of the British Medical Association, filling twelve pages. Its special object is that of developing a plan for bringing hospital service within reach of every person in the British Isles. It was developed by the physicians themselves, and supplements the report of a General Medical Service, an abstract of which was published in the New YORK STATE JOURNAL OF MEDICINE OF July 15, The report is of special interest to to the physicians of New York State in view of the great extension of hospital facilities in recent years, and especially the proposals of State aid for general hospitals in rural communities.

General Principles: The general principles of the hospital plan of the British Medical Association are stated in the introduction, as follows:

"Among the social changes of recent years, none is more remarkable than that which has taken place in our hospitals. Originally charitable institutions for the general treatment of the very poor, they have become centres of highly specialized and complex service to which four-fifths of the population look for help and where the community as a whole claims as a right, service which can only be rendered by a great organization or its dependent branches. Voluntary hospitals have become increasingly the hospitals of the worker and his dependents. There is an urgent national demand that the benefits of the fully staffed and equipped hospital shall not be denied to any class in the community, and in particular shall be available at reasonable rates for those who cannot meet the cost of private nursing homes, and whose means are yet above the income level of the insured person.

"Hence arose the movement to attach paybeds to voluntary hospitals and poor law hospitals in various parts of the country. Hence also the demand for hospital accommodation for another class of case, namely, that which could be tended by a general medical practitioner in the home, but would be better served if that practitioner could attend the patient in a hospital where nursing facilities and auxiliary services could be economically provided, and where, when necessary consultative service of all kinds could be more speedily available and by reason of apparatus and equipment perhaps more efficiently given. Such accommodation is called for in connection with council and voluntary hospitals for patients of the contributing and private groups hereafter defined. It is in the interests of the progress of medicine that a closer relationship between the profession as a whole and the hospitals of the country should be developed.

"The British Medical Association recognizing that hospital accommodation in any given area may be provided by voluntary bodies or by statutory authorities, or by any combination of these, believes that the continuance of voluntary hospitals is in the public interest. The Association is concerned especially to see that in all cases certain fundamental conditions are met:

- "1. that the accommodation be utilized for the provision of those medical services which in the best interests of the patient can be given only in an institution;
- "2. that the arrangements for the medical staffing of these hospitals be such as meet with the considered approval of the medical profession;
- "3. that the normal method of admission of patients to hospitals should be on the recommendation of a medical practitioner;
- "4. that so far as practicable, all hospitals should be available for purposes of medical education."

In a general way the plan recognizes three classes of cases:

- 1. Those who can pay full hospital charges.
- 2. Those who can pay part of the charges.
- 3. Those who cannot pay anything, but are under the operation of the "Poor Law."

The report makes frequent reference to "Council" hospitals, by which are meant those supported by public funds, especially those which were operated under the poor law.

Hospital Charges: The plan provides for the payment of all hospital charges, and says:

"It is laid down in the Local Government Act, 1929, that the local authority must recover from every hospital patient the whole of the expense incurred in the maintenance and treatment of such patient, or if the authority be satisfied that the person cannot reasonably

pay the whole, then such part, if any, as that authority decides he or she is able to pay. The local authority may, however, by agreement with any association or fund (such as a Hospitals Savings Association or Contributory Fund) accept an agreed sum for the hospital expenses in respect of any member thereof.

'In both the voluntary and council hospitals the worker and his dependants must be asked to pay the maintenance and treatment charges appropriate to their financial status. There is no doubt that alike for the prospective patient and for the hospital an agreed payment under a contributory scheme organized by a responsible committee in the area offers the simplest and most satisfactory method. It relieves the patient from irksome enquiries and financial stress at the time of illness, lessens the administrative work of the hospital, and in the case of voluntary hospitals will solve the financial difficulties which beset so many hospitals in large industrial communities.

"Persons insured under the National Health Insurance Acts, and other persons below an agreed income limit may be accepted for hospital treatment as contributing patients on a contributory scheme agreement, or on individual payment, or under a financial arrangement made with Public Authorities, approved societies, employers of labor, insurance companies, and others. The great majority, probably 80 to 85 per cent of all hospital patients, can thus be dealt with, and the hospital services can be adequately financed by one or other of these methods.

"All persons above the agreed income limit should be regarded as private patients, and should be prepared to meet the special charges for maintenance and medical services appropriate to that class. Such persons do not normally constitute more than 5 per cent of applicants for hospital services."

Pay of Physicians: Pay for all medical services is suggested as follows:

"In council hospitals the medical staffs, whether whole or part time, have in the past been paid by salary or on a basis of remuneration for work done. In voluntary hospitals the visiting staff has in the majority of instances been honorary, payment being made only for certain classes of work, in particular that done for local authorities, or under the auspices of government departments.

"It is certain that local authorities must continue in their council hospitals some system of paid medical staffs, whether whole or part time. If the voluntary hospital system is to persist and even more of demands for expansion are to be met, the visiting staffs must be paid on a like basis. Every extension of hospital service diminishes the field of private practice open to consultants and specialists, and economically it is no longer possible largely to increase the numbers of these practitioners without making definite provision for reasonable remuneration for their hospital work. It is in the public interest that there should always be available sufficient hospital personnel to subserve the needs of the community for domiciliary consultations and other services outside the hospital. In general, these needs will best be met under a hospital system where there is part time service by visiting staffs."

Cooperation of Council and Voluntary Hospitals: The report recognizes two classes of hospitals, as in New York State, as follows:

1. Council hospitals, or those operated by municipalities.

2. Voluntary hospitals.

The report quotes the law as follows:

"The Council of every county and county borough shall, when making provision for hospital accommodation in discharge of the functions transferred to them under this part of this Act, consult such Committee or other body as they consider to represent both the governing bodies and the medical and surgical staffs of the voluntary hospitals providing services in or for the benefit of the county or county borough as to the accommodation to be provided and as to the purposes for which it is to be used."

The report continues: "The Association, however, does not consider that a satisfactory scheme of co-ordination can be attained by purely consultative measures, and is of opinion that the local authority on the one part and the Voluntary Hospitals Consultative Committee on the other part ought to set up a body which should have amongst its functions the following:

"(a) to devise means for the co-ordination of admission and transfer of in-patients, as for example, the establishment of a central clearing house or bureau, and the co-ordination of the ambulance transport service in its area;

"(b) to advise on the development of any new hospital accommodation for the area; but these joint bodies should in no way interfere with the autonomy of the hospitals within their area as to

I. Finance;

II. Management;

III. Election of Governing Body and Medical and Surgical Staffs."

Central Hospitals: The report proposes a central hospital for each area, as follows:

"The Association envisages a hospital system in which all hospitals in a given area will be grouped round a central or base hospital.

In the existing state of affairs the central or base hospital will generally be one of the larger voluntary hospitals. This may or may not be the locus of a medical school, but will in any case be expected to set the standard of hospital practice in the area and be the chief centre of education and research.

"Before a hospital could be said to occupy the position of a central or base hospital, it should fulfil one or other of the following con-

ditions:

"I. It should be a hospital with which a recognized medical school (under-graduate or

post-graduate) is associated, or

"II. It should be a general hospital (voluntary or council), other than one associated with a medical school, which:

- "(a) has outstanding advantages as regards staff and equipment, and is of sufficient size:
- "(b) acts as a consultative centre;

"(c) deals with the investigation of the more difficult cases; and

"(d) undertakes the more specialized methods of treatment."

"All the other hospitals in the area, including special and cottage hospitals, should be grouped round the central or base hospital and

be co-ordinated with it.

"The council hospital, as the hospital under the control of the local authority which has a direct responsibility for providing institutional treatment when necessary must provide accommodation for those cases which are outside the province of the voluntary hospitals. Where the voluntary hospital is already holding the leading position and is progressive and locally supported, it should maintain this position; and any further developments which are necessary in the area, should be made in co-operation with it. The council hospital, where not itself the central or base hospital, should develop not in wasteful competition with, but in co-ordination and co-operation with, .the voluntary hospital."

Council Hospital Policy: The policy of the council hospital is stated as follows:

"The continued provision of services for those types of illness which form the bulk of cases dealt with in poor law hospitals is now a primary function of council hospitals. Increased hospital provision for acute medical and surgical cases however will be found necessary within their areas by most local authorities. In the more populous centres it will probably be agreed that the acute class of case such as now constitutes the majority of the patients of a large voluntary hospital is best dealt with in separate wards, blocks, or institutions.

"The responsibility for the treatment of certain types of case will doubtless remain as at present with the whole-time resident staff. In some units the present mode of staffing with free use of a consultant visiting staff will be economical and efficient. It is advisable, however, to ensure full co-operation with the voluntary hospitals wherever large numbers of acute cases have to be dealt with by having a part-time visiting staff of similar status and in similar numbers to those of the large voluntary hospitals."

The report then states that the staff of a

council hospital should consist of

 a whole-time medical superintendent in full charge of admissions of patients, the supervision of the medical assistants, and the administration of the hospital;

assistant physicians;

a part-time consulting staff;

 clinical assistants from among the practicing physicians of the area.

Voluntary Hospital Policy: The report states:

"The Association recognizes a dual policy as regards the voluntary hospitals: (a) that the purely charitable side should be continued wherein the whole cost of the maintenance of free patients is met by the gratuitous contributions received by the hospital and on whose behalf the services of the visiting medical staffs are given gratuitously: (b) that patients other than free patients may be received for treatment at voluntary hospitals and that for them payment should be received by the hospital, either from the patients themselves, or on their behalf from the authority or body referring them to the hospital, and that on account of their treatment, suitable methods of remuneration of the visiting medical staff should be arranged."

Sources of Funds: Funds may be received by hospital managers from two sources:

"(a) Gratuitous contributions, i.e., contributions from whatever source to which no such conditions are attached (either expressly or by implication) as would involve obligation of service on the part of the hospital, but are charitable contributions to be expended at the discretion of those to whom the management of the hospital is entrusted;

"(b) Contributions for services or to be rendered, i.e., contributions for hospital benefit made either by patients themselves or on their behalf by individuals or associations, or in the case of local authorities payment made for the maintenance and medical treatment of patients for whom these authorities are re-

sponsible.

"It is undesirable that hospitals should themselves undertake any insurance risk in connection with hospital services, i.e., undertake to provide hospital benefit when required in return for periodic payments, individual or massed. Schemes set up to provide payments for hospital benefit should be organized and managed not by the hospital, but by some independent outside body which would be responsible for such payment in the event of a member of the scheme receiving hospital services."

Free Patients: The policy regarding free patients is stated as follows:

"Where persons receiving hospital service are certified by the almoner or other officer of the hospital as unable to contribute in any way towards their maintenance and medical treatment, hospital benefit should be provided by the gratuitous contributions placed at the discretion of the hospital managers and by the gratuitous services of the visiting medical staffs."

Contributing Patients: The report says:

"Applicants for hospital benefit, not being free patients, whose income does not exceed a specified local scale should be given service on terms appropriate to their financial position, always provided that the payments made shall be understood to be in respect of both maintenance and treatment, and that the visiting medical staff shall receive from the hospital managers remuneration for such service either by salary, by honorarium, or by agreed payments to a staff fund placed at their disposal.

"The ordinary hospital routine of admission, transference and discharge of patients should not be modified for contributing patients, nor should any preferential treatment be given to

them."

Out-Patients: The policy as regards outpatients is stated as follows:

"The primary object of the Out-patient Department should be for consultation.

"Only such treatment should be given as cannot in the best interests of the patient be obtained elsewhere under the usual arrangements as between private practitioner and private patient. Cases not accepted for treatment should be referred (in general terms) to

a medical practitioner, to a public medical service, an approved provident dispensary, or to the public assistance officer of a local authority.

"Where arrangements for consultations or specialist services for patients are made under some contributory scheme or otherwise, such arrangements should provide that these services shall be given, so for as possible and consistent with the best interests of the patients, by the private practitioner at his consulting rooms or at the patient's own home, and not at the Out-patient Department of the voluntary hospital.

"Private patients should not be seen or treated at the Out-patient Department of a voluntary hospital, except where no other arrangement is practicable, or in case of emergency, and in such cases paragraph 3. (c) of Appendix B should govern arrangements.

"In cases where consultations or treatment are given at an Out-patient Department, the ordinary hospital routine should not be modified nor should any preferential treatment be given to contributing or private patients."

Appendices: The report concludes with six pages of appendices, which outline the following subjects:

1. Model contributory insurance scheme.

2. Conditions of admission and treatment of private patients in hospitals.

Contributory schemes for private patients.

4. Standards for hospitals with one hundred or more beds.

5. Medical staffs of hospitals.

Private patients in independent hospitals.

7. Provision for maternity cases.

8. Provision for radiological services.

9. Provision for pathological services.

10. Local hospitals advisory medical committees.

It is apparent that the evolution of hospitals in England is far in advance of that in the United States. Any group of physicians in New York State that is planning a scheme for hospital development will find a precedent in the experience of their English brethren.

#### LAKE KEUKA MEDICAL AND SURGICAL ASSOCIATION

The Lake Keuka Medical and Surgical Association embracing nearly all the counties in the western half of New York State, held its thirty-first annual meeting on July 10 and 11, in Keuka Hotel on Lake Keuka. This is the great local event of the summer, both scientific and social, among the doctors of the western counties. Several hundred doctors and their wives attended the two-day session.

The first session was opened on July 10th at 9.30 A.M. with the President, Dr. Floyd S.

Winslow, presiding.

Dr. W. D. Johnson of Batavia, N. Y., President-elect of the Medical Society of the State of New York, brought the greetings of the State Society.

The scientific program on the morning of July 10 consisted of a symposium on Intestinal Obstruction, at which the speakers were Dr. W. G. Farlow, Dr. C. V. Costello, Dr. Floyd S. Winslow, and Dr. H. L. Prince, all of Rochester.

The first part of the afternoon session was on The Liver, and the speakers were Dr. C. G. Heyd, New York, Dr. Donald Guthrie, Sayre, Pa., Dr. T. B. Jones, Rochester, Dr. I. H. Leyy, Syracuse and Dr. A. H. Aaron, Buffalo.

The second half was on Cardiac Pain, and the subject was introduced by Dr. Louis Faugeres Bishop, New York City, and discussed by Dr. N. G. Russell, Buffalo, Dr. W. S. McCann Rochester, Dr. Allen Holmes, Watkins Glen, Dr. Charles Post, Syracuse, and Dr. C. W. Greene, Buffalo.

Two sessions were held on the morning of July eleventh. The first was on the subject, "Sterilization for Human Betterment," and was introduced by Dr. Floyd R. Wright, Clifton Springs Sanitarium. It was discussed by Dr. A. H. Paine, Rochester, Dr. J. O. Polak, Brooklyn, Dr. H. A. Steckel, formerly Superintendent of the Newark State Hospital, and Dr. Royal S. Copeland.

The second part of the morning program was on the subject "Present Day Practices in Obstetrics and Gynecology," which was introduced by Dr. J. O. Polak, and discussed by Dr. Karl Wilson, Rochester, Dr. James King, Buffalo, and Dr. H. W. Schoeneck, Syracuse.

A warning against state control of medicine was given by Dr. W. H. Ross, of Brentwood, President of the Medical Society of the State of New York. Dr. Ross spoke of the extension of state aid in local health projects, and of the commission appointed by Governor Roosevelt to study the health laws of New York State in a comprehensive way and devise a new unified system of legislation to be introduced in the next Legislature. The practicing physicians of New York State have only a very small representation on that commission. Dr. Ross urged the physicians to take a personal interest in the new movements rather than permit themselves to be overwhelmed by the rising tide of socialized medicine directed by non-medical leaders.

Dr. Frank Leopold of Buffalo was elected President, and Dr. John A. Hatch of Penn Yan

was reelected Vice-President.

#### ONEIDA COUNTY

Sixty doctors of the Oneida County Medical Society in their April meeting at the Hotel Utica, with President Hubbard in the chair, unanimously gave support to a campaign that is being waged in the city against diphtheria in the following resolution;

"Whereas, in view of the fact that at this time the Health Department, and the Schools of Utica in co-operation with the State Department of Health, are making a special effort to extend the benefits of toxin antitoxin immunizations against diphtheria to as many children as possible of preschool and school age:

"Resolved, that we, the Medical Society of the County of Oneida, wish to go on record as heartily endorsing the movement which is to be carried on in Utica the week of April 28th, and the two following weeks

outlined the bills at present before the Assembly

following weeks.

Dr. W. B. Roemer, reporting for the Legislative Committee of the County Medical Society,

and urged the members of the Society to keep in touch with their respective Legislators.

The Public Relations Committee, whose report was presented by Dr. T. H. Farrell, outlined the interest that is being aroused in the community toward periodic health examinations. These examinations are to be made yearly by the family physician, and constitute a health check-up such as has been already instituted by a number of the larger life insurance companies.

Dr. Farrell called attention to the series of industrial health talks which were given to eight industrial concerns, averaging six lectures each, at which the total attendance was nearly eight thousand persons, and an average attendance of one hundred and sixty. Several of the industries have asked for similar courses to be sponsored by the Oneida County Medical Society, and the Utica Dental Society, during the coming year. The arrangements for this course were made by

Mr. Monte Beard, the Industrial Secretary of the Y. M. C. A.

930

Dr. Farrell outlined a proposal for a county health unit for Oneida County which would place the present health organizations under a full time health officer, thus securing executive cooperation with the administration of all health activities throughout the county.

Dr. Paige E. Thornhill of Watertown, President of the Fifth District Branch Medical Society, was present at this meeting and commended the Society for its activity in public health work.

Dr. Irving Swartz of Camden was elected to membership.

The Scientific Program consisted of a technical talk by Dr. E. M. Stanton, F.A.C.S., of Schenectady, on the subject "Gall Bladder Disease." Dr. Stanton gave statistics proving the high percentage of gall bladder disease at the present time, drawing conclusions to show the tremendous advances made in this branch of surgery in the past few years.

Dr. A. L. Sontheimer, D.D.S., of Rome, N. Y., talked on the subject of "Tic Douloureaux" illustrated with motion pictures showing the technique of operation, and discussion of the various forms of this painful and distressing malady.

WILLIAM HALE, JR., Secretary.

## WYOMING COUNTY

A special meeting of the Wyoming County Medical Society was held on the morning of July eleventh to take action on the suggested plan of organizing the medical work in the county general hospital which had been authorized by the Board of Supervisors.

The physicians of Wyoming County had been working for some months on a plan by which the County could purchase the Wyoming County Community Hospital in Warsaw, and conduct it as a county project. The hospital was well equipped and managed, but the sparseness of population did not permit the hospital to be self-supporting, although it filled a very real need in the county. The Committee on Public Relations of the Medical Society of the State of New York took a deep interest in the proposed hospital, as it also did in the public hospital for Lewis County. The Committee consulted the State Department of Health regarding the possibility of extending State aid to the county on the ground that the hospital would be a great promotor of public health. (For the law see this Journal December 15, 1929, page 1522.)

Plans were perfected in the fall of 1929, and a bill was passed by the Legislature permitting the Board of Supervisors of Wyoming County to purchase the Community Hospital for \$80,000, without the formality of submitting the proposition to a referendum of the voters. The State Department of Health also arranged that it would pay one-half of the cost of the hospital, if Wyoming County would take it over. The Board of Supervisors authorized the

purchase of the hospital at its meeting of June 28. The plans were quietly perfected and on the evening of July tenth a good will dinner, attended by over sixty persons, was held in celebration of the establishment of the hospital. Dr. Parran, State Commissioner of Health, and Dr. W. H. Ross, President, and Dr. W. D. Johnson, President-elect of the

Medical Society of the State of New York, had spent the afternoon consulting the county officials in regard to the hospital. The dinner was attended by the leaders in business and civics, and by representatives of the medical profession.

Since the dinner demonstrated the deep interest of the civic leaders in the hospital, the obvious step was that the physicians of the county should formulate a plan for carrying on the medical and surgical work of the hospital. A special meeting of the Wyoming County Medical Society was accordingly called for noon on July eleventh. This meeting was attended by nearly every one of the thirty-two members of the Society. The meeting was addressed by Dr. W. H. Ross, President of the Medical Society of the State of New York, who outlined the standards of organization which have received universal approval. He emphasized especially the need of (1) a small Medical Board to be the executive committee of the doctors; (2) monthly staff meetings; (3) complete records of all patients; and (4) the adoption of rules and regulations for enforcing these standards. Standards of organization were suggested by the Committee on Public Relations of the State Society (see this Journal December 15, 1929, page 1522); and the meeting voted to support the following general plan.

1. The staff should consist of every qualified physician in Wyoming County who is in good repute and a member of his County Medical Society.

2. The County Medical Society should appoint a Medical Board of five physicians who should have the powers and duties of leadership, which ordinarily devolve on similar boards in general hospitals.

The Wyoming County Medical Society has set an example which will doubtless be followed by the societies of other small counties.

### BRONX COUNTY MEDICAL SOCIETY

The Annual Meeting of the Bron County Medical Society, held at the Concourse Plaza, on June 18, 1930, was called to order at 9 P M., the President, Dr. Aranow, in the Chair

The following doctors were elected members: Drs. Harry M. Berliner, Irvin C. Bronstein, John Cohen, Arthur Ettinger, Abraham Halberstein, Jacob O. S. Jaeger, Aaron Arnold Karan, Irene Pieper Koenig, Rolfe Longobardi, Moses H. Marton, Samuel Melamed, Leonard Orens, Peter-Cyrus Lewis Rizzo, Samuel B. Suskin, Francis W. Vaccarino and Stanley M. Wershof.

Annual Reports for the year 1929-1930 were submitted as follows:

Secretary, Dr. Landsman.

Comitia Minora, Dr. Landsman, Secretary.

Treasurer, Dr. Keller.

Board of Censors, Dr. Bookman, Secretary. Counsel, Dr. Booxbaum.

Committee on Bulletin and Publicity, Dr.

Podvin, Chairman. Committee on Membership, Dr. Weitzner,

Chairman.

Committee on Public Health and Medical Education, Dr. Goldman, Chairman.

Committee on Medical Economics, Dr.

Magid, Chairman.

Committee on Audit, Dr. Ambos, Chairman. Milk Commission, Dr. Golomb, Chairman. Committee on Legislation, Dr. Flynn, Chair-

Committee on Hospitals, Dr. Leiner, Chair-

Relief Committee, Dr. Henry Roth, Chair-

Special Committee on New Members, Dr. Bick, Chairman.

Building Committee, Dr. Amster, Chairman. Committee on Health Examination, Dr. L. Friedman, Chairman.

Special Committee on Laboratories, Dr. Git-

low, Chairman.

Special Committee on Physio-Therapy, Dr. Grossman, Chairman.

It was moved and carried in each case that the Report be accepted with thanks.

The President, Dr. Aranow, then expressed his appreciation for the work done by the Committees during his Administration.

Action on the following Amendments, introduced at the last meeting of the Society, was then declared in order:

Add to Section 4, beginning at nineteenth

"Internes serving in Bronx Hospitals are also eligible for Associate Membership in this

It was moved and carried that the above

Amendment be adopted. Add Section 26 (a): "Applications of Internes for Associate Membership shall state college from which graduated, with date and hospital affiliation. An affirmative vote of two-thirds of the votes cast at a regular meeting of the Society shall be necessary to elect."

It was moved and carried that the above

Amendment be adopted.

The following resolution was introduced:

"Whereas, The Bronx County Medical Society having sustained a severe loss in the death of its honored associate and Charter Member, Nicholas Lukin, M D.

"Resolved, That the Bronx County Medical Society record the sense of its loss in the death of Dr. Lukin and that a minute thereof be placed on the records of the Society, and be it

"Further Resolved, That a copy of these Resolutions be transmitted to the family of

our departed member."

Also the following resolution:

"Whereas, The Bronx County Medical Society having sustained a severe loss in the death of its honored associate and Charter Member, Otto J. Scheina, M.D.

"Resolved, That the Bronx County Medical Society record the sense of its loss in the death of Dr. Scheina and that a minute thereof be placed on the records of the Society; and be it

"Further Resolved, That a copy of these Resolutions be transmitted to the family of

our departed member."

The above Resolutions were carried by a rising vote.

Following the Report of the Tellers, the following Officers for 1930-1931 were declared elected:

President, Joseph H. Gettinger; First Vice-President, Irving Smiley; Second Vice-President, William Klein; Secretary, I. J. Landsman; Treasurer, J. Adlai Keller; Board of Censors (2 years), Adolph Rostenberg, Harry Projector; Delegates (2 years), Harry Aranow, Louis A. Friedman, J. Adlai Keller, Edward C. Podvin; Alternates (2 years), William Lenetska, Louis Nagorsky, Charles S. Rogers. Samuel Rosenzweig; Alternate (1 year), Isaias A. Lehman.

The following were elected as members of the Nominating Committee:

Samuel Feldman, Milton R. Bookman, Benjamin Sherwin, Sidney Cohn, David Deutschman, J. Bernard Cohen, Michael Rosenbluth, Joseph O. Smigel, Henry Schumer, Irving B. Krellenstein, Martin J. Loeb.

Respectfully submitted, I. J. LANDSMAN, M.D., Secretary.

### THE MEDICAL FIELD SERVICE SCHOOL

While summer is the time of relaxation, many physicians spend their vacations in Army camps, where recreation is as strenuous as that at a fishing lodge. Our fifty physicians of New York State in the Medical Officers' Reserve Corps spent two weeks at the Medical Field Service School, which occupies the buildings and grounds of the former Indian School at Carlisle, Pennsylvania. The officers of two medical regiments of New York, the 302nd belonging to the 77th Division, and the 350th, belonging to the Second Corps area, went as units, and lived under actual service conditions.

The Reserve Officers recorded their impressions in a camp paper called "The Caduceus" under the leadership of the Executive Editor of the New York State Journal of Medicine. One page of Caduceus consisted of an appreciation of the Commandant of the School, Colonel Charles R. Reynolds, a native of Elmira, N. Y. and well known to many physicians of the State. The appreciation reads as follows:

"Commandant of the Medical Field Service School since August 1st, 1923; the first Division Surgeon of the 77th Division at Camp Upton and overseas, and the organizer of its Sanitary Train, now the 302nd Medical Regiment, whose members have been prominently represented in the Officers' Reserve Corps at Carlisle Barracks since the first class,—July 5th to 19th, 1923.

"Events are biographies, and institutions are the lives of their founders and developers. The Army is typically an institution in which the individual is submerged and the organization is glorified. Yet the Medical Field Service School of the United States Army at Carlisle, Pennsylvania, is seven years of your life,almost a record for the length of service which an officer is permitted to give in one post, however important it be. You have given your time because the Medical Field Service School was necessary, and because you delighted to develop its standards and put them to practice. We come to Carlisle-some of us year after year-because we learn to deal with grave emergencies which arise in times of peace as well as war. We come, too, because we want to see you live and act the practical part of a soldier of peace."

Caduceus also contains the following impressions of the School in 1930:—

"Those Reserve Officers who have attended the Medical Field Service School in former years are gratified with the abundant evidence of the interest of the United States Government in the training of the Medical Officers of the Army. These evidences are plainly seen in the equipment of the school and in its courses of instruction. The most evident improvement has been the provision for the comfort of the Reserve Officers. The tents for their accommodation have been grouped along a macadamized road bordered with cement walks which extend to the washroom and to the assembly halls. Also cement bases have been laid for the tents and comfortable beds with springs and mattresses have been provided. The medical officers expect to live their fortnight in camp with the least possible equipment but they pride themselves on those essentials which eliminate mud and dust and sloppy walks. The officers also appreciate the new mess hall and the courteous service to which they can introduce their wives and daughters with pride. The opinions of the ladies contribute largely to the respect in which the army is held by the people.

"A further impression of culture and refinement has come from the beautification of the grounds. Green lawns and bright flowers give the School the air of a college campus.

"Progress in pedagogical methods has been equally striking and pleasing. This year instruction and administration has been by means of seven Medical Regiments to which members of other organizations have been attached during the training period. Uniform problems have been assigned to each regiment and their officers have had to study them in the same manner that they would solve them as independent commands in actual service. The complete change from the lecture system. to that of the spontaneous solution of problems has aroused a spirit of earnestness and satisfaction which will be reflected in the members when they return home. The knowledge that a detailed service record of each officer is kept has further spurred the men to their best endeavor, for they feel that their efforts are appreciated and that they will progress in their military work and grade in accordance with their demonstrated merit.

"Army life is full of human interest, of humor and good fellowship, of which examples are given in the closing pages of "Caduceus." Here the story teller, the poet and the artist receive the recognition which is only a faint reflection of that which is given to them in the tents, the drill fields and the class rooms.

"Finally, there are about four hundred medical students of the R. O. T. C. units. They, too, give unmistakable evidence of a spontaneous response to the progressive spirit of the Medical Field Service School."

# THE DAILY PRESS

#### HEALTH HAZARDS

A maximum of information with a minimum of words

Briggs in the New York Herald Tribune, April 28, 1930

Briggs in the New York Herald Tribune, June 27, 1930

### A NATIONAL HEALTH INSTITUTE

Physicians sometimes have to go to the daily newspapers for medical news. The editorial page of the New York Times of May 24th has the following description of important health legislation, recently passed by Congress:

"Blanketed by the debates over the tariff, the treaty and the Supreme Court, a bill has slipped through Congress, almost unnoticed, which will have a place in governmental history. It sets up a National Institute of Health. This has long been the dream of Senator Ransdell of Louisiana. In realizing it, he has had the support of the American Medical Association, the American Public Health Association and various scientific bodies. His bill has the endorsement of Secretary Mellon and will doubtless be signed by President Hoover, who has always taken a special interest in scientific research and in government agencies to further it.

Under the Ransdell bill the Hygienic Laboratory is made the nucleus of the new establishment, which will be devoted to the purpose of inquiring into the cause, prevention and cure of diseases.

"While a great deal has been accomplished by the universities, medical schools and endowed institutions, these efforts heretofore have often lacked coordination. The idea is to make the institute 'a great cooperative scientific organization in which leading experts in every branch of science will be brought together and given an opportunity to work in unison for the purpose of discovering the natural laws governing human life."

#### ALCOHOL AND HEALTH

It is strange that no great investigation into the effects of alcohol upon the human body and mind has ever been made; and yet prohibition is one of the most important prob-'ems of the day. The New York Times of June 22 exactly expresses the opinion of the physicians of New York State where it says editorially;

"With all the surveys going, it would seem that, in the present bewilderment over prohibition, one suggested by Professor Percival Symonds at the Child Health Conference should be added-an impartial scientific study of the physiological and biological effects of the use of alcohol. If there were an authoritative and indisputable decision concerning

them, there would be firm ground on which to proceed to consider the social effects.

"As it is, there are conflicting views even among doctors. The layman is in doubt whether the chemical changes worked in the human body by alcohol, if it is not used in excess, are deleterious. The testimony of Sir George Newman, before the Royal Commission on Licensing, is recalled:

"I know of no scientific evidence to support the view that alcohol increased or fortified the natural powers of resistance of the body to infective processes, or that alcohol directly

strengthened the tissues of the body.

"In view of the universal interest in the

subject of prohibition, pro and con, there is no subject upon which the advice of the highest authorities would be more generally welcome—even if it should prove disappointing to one or the other of the interested groups. For when the physiological and biological effects are determined, the moral values will appear. On the basis of the results of such a study social policy in controlling the use of alcohol could be framed with some hope of a supporting public opinion. Obviously, such a study must be made by scientists whose findings will be accepted as disinterested and dependable. Here is an opportunity for some foundation to do a great public service."

### CHILD APPETITES

The New York Times of June 27 comments editorially on researches in child feeding conducted by the Department of Home Economics of the University of Chicago, and said:

"The research workers used several groups of small children, some in nursery schools, others in orphanages. It was easy to fix the kind and amount of food each child should eat, but getting them to consume every bit of it was another matter. The orphans, who had formerly gobbled everything set before them as fast as they could, soon discovered that it was important to those in charge for them to eat all their food, and in less than a week they had become 'as perfect a set of dawdlers as could be found in any of our best homes.'

"Solicitude that a child may observe in his mother about his diet is bad for his appetite. Her anxiety for variety in his food is not only responsible for his captiousness, but seems to be entirely unwarranted. A group of small children used in one experiment had exactly the same breakfast dinner and supper every day

for three weeks. Canned peaches were the dessert every day for both dinner and supper. At the end of the study they were given a party, with entirely different food, ice cream, and a cake with candles.

"They expressed delight at the candles, but not one mentioned any of the food. Then the dear little creatures of habit, having finished their ice cream, asked, 'Where are the peaches?' Another group, a little older, showed the same fondness for monotony at the conclusion of a similar experiment. These children were told that they could choose anything they liked for a picnic, and they asked for the very things they had been eating constantly for three weeks."

When children go home from hospitals, their parents often complain that the children's appetites have been spoiled because they will not eat ice cream and other pastry, while they continue to be greedy for spinach, and carrots, and other simple foods on which they throve in the hospital.

# BOOK REVIEWS

THE PRINCIPLES OF LLECTROTHERAPY AND THEIR PRACTICAL APPLICATION BY W J TURRELL VIA, D M, B Ch Second Edition Octavo of 413 pages London and New York, Oxford University Press, 1929

In this timely book, Dr Turrell presents to us a vast fund of knowledge gleaned from his actual experience in electrotheripy. Many of the details are not in accord with generally accepted tenets and usages, but they must be regarded as the conclusions of a worker who has actually found them true or otherwise.

There are interesting chapters devoted to the history, methods and apparatus of electrotherapy. The chapters describing the freatment of nerve lesions and discases is of particular value. The concluding chapter on practical hints and methods brings to us first hand the details which only years of experience can accumulate.

The book is well written and clearly illustrated and printed, and will be a valuable addition to the medical library

JEROME WEISS

THE STORY OF SAN MICHELE By AXEL MUNTHE Octavo of 530 pages New York, E. P. Dutton and Company, 1929 Cloth, \$375

Dr Munthe, a Swedish physician, has written an extremely fascinating biography of his life. Its title The Story of San Michele," represents a lifelong desire to erect a dream castle in a region of Italy which in his youth had kindled his imagination and ambittons

After his graduation at Paris, he enjoyed an especially intimate friendship with such famous men as Charcot and Potain, and later became prominent as a fashion able society doctor. His patients and friends included counts and princes, the Rothschilds and, from recent newspaper accounts, the Queen of Sweden. His book dwells at length with certain of the evils of society and with the imaginary ills that often afflict the idle rich. After a short time in practice, he found that "what they all liked was appendicitis" and after a period of discouragement he had managed to succeed with psychotherapy, suggestion a laying on of the hands, and by a suave manner which according to his account was very soothing

And so while Munthe's account strikes an harmonious note in its incidences which we professional men at some time or another feel, there is a certain departure from the beaten trails of routine professional practices which lends an added flavor. His love for animals is intense and he frequently carries on lengthy and imaginary conversations with his animal friends. His love for art is ardent. At times his style is distinctly fantastic and unreal and one wonders whether this is a true biography or a dream story.

Dr Munthe has painted a very interesting life story

EMANUEL KRIMSKY

METHODS AND PROBLEMS OF MEDICAL EDUCATION (Fourteenth Series) Quarto of 207 pages, illustrated New York, The Rockefeller Loundation, 1929

The Fourteenth Series of the Rockefeller brochures is given over to the detailed record system of the Massachusetts General Hospital in a case of fracture. The records of the Childrens' Hospital, Cincinnati, are eproduced as well, and the working of the Department of Public Health and Preventive Medicine in Peking Union Medical College is described. A good volume for the frieture surgeon. C. A. G.

CORONARY THROMBOSIS ITS VARIOUS CLINICAL FEXTURES By SAMUEL A LEVINE. Octavo of 178 pages illustrated Baltimore The Williams & Wilkins Company, 1929 Cloth, \$300 (Medicine Monographs v 16)

Coronary occlusion is a common and very important medical accident. Its recognition and appropriate treatment not infrequently make the difference between death and recovery. Our knowledge of it is largely of recent acquirement. A brief but comprehensive monograph on the subject was overdue. Dr. Levine, who has made important contributions in this field, was well chosen to present it, and has succeeded in compressing much in formation into little space. There are indications, however, that it was hurriedly done. A lessurely revision will improve it. Some recent developments in the electrocardiographical aspect of the subject should be added to bring it up to date.

DEGENERATION AND REGENERATION OF THE NERVOUS SYSTEM BY S RAMON Y CAJAL, M D F R S Translated and edited by RAOUL M MAY, Ph D Two octavo volumes of 769 pages, illustrated London Oxford University Press, 1928 Cloth, \$1675

The Spanish school has long been recognized as the center for the cytological study of the nerve cell. Investigators from all over the world have considered it a great privilege to visit Cajal's Laboratories and to have an opportunity to study under lins supervision. Now he has turned out a masterpiece in the present volumes, Degeneration and Regeneration of the Nervous System. These two volumes are welcomed as there is nothing in the English language that so completely covers the subject. These two volumes are necessary and essential for every medical library of hospitals, medical schools and medical men who are interested in neurology, neuro surgery and neuroantomy.

AN INTRODUCTION TO EXPERIMENTAL PHARMACOLOGY By TORALD SOLLMANN, MD, and PAUL J HANZLIN, MD Octavo of 321 pages Philadelphia and Lon don, W B Saunders Company, 1928 Cloth, \$4.25

This is a most excellent text on practical pharmacology, a compilation of experiments showing the action of drugs that are used at the present time. The experiments are well devised and clearly described, and the methods given illustrate the technique of pharmacologic investigation as well as the action of drugs. The appendices, of which there are fourteen, are a special feature for much of the data given here are scattered through the literature and very difficult to locate.

A G

APPLIED PHARMACOLOGY By A J CLARK, M C., B A, M D Third Edition Octavo of 529 pages, illustrated Philadelphia, P Blakiston's Son & Company, 1929 Cloth, \$4,00

This very meaty volume of 500 pages presents Applied Pharmicology in a mainer somewhat new to the American Physician Indeed, Applied Pharmacology as apart from Pharmacology, has been one of our neglected subjects, even Applied Therapeutics has been slow in coming to the front as a distinct branch of science

Dr Clark's work shows a broad knowledge of the subject in its more scientific aspects and his style makes for an enjoyable reading. A non contraversal preentation of so technical a subject is rare. The modern intermist will profitably add this volume to his working hibrary.

		700.00

Total Journal Fund Expenses ......\$31,262.55

Concerning the Journal, the report of the Trustees says:

"As an evidence of what can be done in the matter of cutting down expenses, our publishers found that by purchasing a year's supply of paper we could secure a grade of paper which will reproduce half-tones quite satisfactorily, and at a price less than the present arrangements produce, wherein a supply for three months at a time, only, is secured. The procedure now is to use the calendered paper only in the forms where there are to be illustrations. This saves the cost of paper but adds to the cost of production. Under the new arrangement it is felt that a better appearance will be presented and at less cost. Likewise, by careful analysis of the cost of production, the publishers have been able to reduce the prices on reprints a flat ten per cent over the old schedule. This is for the convenience of our contributors. We do not furnish reprints free. Our publishers are under contract with us to furnish them to the contributor at the exact cost. Heretofore the Journal has used the same paper in its cover form as is used for illustrations throughout the book. The Trustees feel that a cover differing in texture and color from that used for the advertising pages, will be an improvement in appearance and add something to the worth of the publication. By purchasing a large supply of this material, this improvement can be made at practically no additional cost. It will doubtless be done."

The Trustees also authorized an exhibit of the files of the Texas Journal together with those of all the other States.

# COMMITTEES ON PUBLIC HEALTH IN SOUTH CAROLINA

The report of the Committee on Medical Economics of the South Carolina Medical Association recorded in the Journal of June, deals largely with the practice of preventive

medicine, and says:

"While it is very evident that the activities of the public health agencies have advanced beyond preventive medicine and health education, and are slowly but steadily entering the field of curative medicine, the blame for this state of affairs cannot be placed wholly on the public health agencies. The medical profession is partly responsible in that there are yet quite a few in our ranks who refuse to take an active part in matters pertaining

to preventive medicine, and we have, therefore, failed to assume for organized medicine its rightful place as the leader in all things which pertain to the health of the public, sick or well.

"Before we can insist upon the direction of all medical and health matters, we must as an organization, prove our capability and willingness to do so, and we must carefully avoid any semblance of commercialism replacing that altruism which belongs alone to the medical profession. Your Committee believes it possible to so coordinate the work of the public health agencies and the family physician, giv-

# HAY FEVER

# An Advertising Statement

HAY FEVER, as it occurs throughout the United States, is actually perennial rather than seasonal, in character.

Because in the Southwest—Bermuda grass, for instance, continues to flower until December when the mountain cedar, of many victims, starts to shed its pollen in Northern Texas and so continues into February. At that time, elsewhere in the South, the oak, birch, pecan, hickory and other trees begin to contribute their respective quotas of atmospheric pollen.

But, nevertheless, hay fever in the Northern States at least, is in fact seasonal in character and of three types, viz.:

TREE HAY FEVER—March, April and May GRASS HAY FEVER—May, June and July WEED HAY FEVER — August to Frost

And this last, the late summer type, is usually the most serious and difficult to treat as partly due to the greater diversity of late summer pollens as regionally dispersed.

With the above before us, as to the several types of regional and seasonal hay fever, it is important to emphasize that Arlco-Pollen Extracts for diagnosis and treatment cover adequately and accurately all sections and all seasons—North, East, South and West.

FOR DIAGNOSIS each pollen is supplied in individual extract only.

FOR TREATMENT each pollen is supplied in individual treatment set.

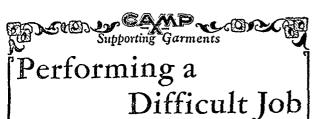

ALSO FOR TREATMENT we have a few logically conceived and scientifically justified mixtures of biologically related and simultaneously pollinating plants. Hence, in these mixtures the several pollens are mutually helpful in building the desired group tolerance.

ing the latter an active part in preventive medical work, as to make of each County Medical Society a local County Board of Health; and we believe further that steps should be taken to make the County Medical Societies feel their responsibilities as guardians of the public health. When this is done, all public health work will naturally look to the Medical Society in the community for direction and leadership. To this end we respectfully recommend:

(1) That each component County Medical Society making up the South Carolina Medical Association be instructed to appoint or elect a Committee on Public Health, whose duty it shall be to supervise and cooperate with any and all agencies doing work of a preven-

tive or public health nature in its County.
(2) That the Health Officer in each County employing a complete health unit, make a written report of his activities to the Medical Society of the County in which he is working, once each month or when such report is made to the State Board of Health, and that the Medical Society cooperate with him in his work, through its Committee on Public Health.

(3) That any nurse or public health worker employed in a County that has no public health officer or physician at the head of its health department, be responsible to and work under the supervision and direction of the Committee on Public Health of the Medical Society of the County in which he or she is employed.

(4) That the State Board of Health, Bureau of Infant and Maternal Welfare, and all other agencies holding clinics of any and all kinds, be requested not to conduct any clinic in any County of the State, except with the consent and at the invitation of the Medical Society of the County in which the clinic is to be held, and that the members of the Medical Society be asked to participate in any clinic held in its County,

(5) That all prophylactic vaccinations, inoculations and administrations of serums, vaccines, antitoxins, etc., be given by a regularly licensed and practicing physician, although distributed by the State Board of Health, and that no Health Officer administer such biologicals in "wholesale" numbers until careful investigation has been made as to the ability of those taking such biologicals to pay for the administration of the same.

(6) That each County Medical Society be urged to release to the press for publication such written matter concerning preventive medicine, public health measures, the control of disease, the prevention of accidents, and

medical articles dealing with the subjects in which the public is interested; such articles to be written by a member or members of the Medical Society, to be reviewed by the County Medical Society, and to appear over the signature of the County Medical Society and not the individual writer. (We herewith apologize to the Committee on Public Health and Instruction for this recommendation, but we believe that this is an economic question, since in this way the Medical Society can ethically increase the work of its members and can assume its rightful position in the community as the adviser to the public in all things medical)."

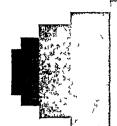

The suggestions of the South Carolina Medical Association cover the same points which occupy the attention of the county medical societies of New York State. It is gratifying to find that the objects and methods of medical societies are uniform throughout the nation.

## PUBLISHING NAMES OF MEMBERS IN TEXAS

The May issue of the Texas State Journal of Medicine has the following editorial on the publication of the names of the members of the State Medical Association of Texas:

"The June Journal will carry a list of members in good standing up to the actual time of going to press, approximately June 1. Therefore, it is still not too late to pay dues. course, where county societies have already made their annual reports, those who have not paid until now will be denominated, technically and necessarily, as not members from January 1 up until the time they actually pay dues. That is not as bad as it will be if the non-membership period is extended to include the entire year. More and more that part of the public which has to do with physicians is relying upon county society membership. Some complaint has been heard. here and there, that such membership is too ex-That is ridiculous. It may be more expensive than it should be, but certainly the advantages to accrue from county society membership are worth the \$10.00 the State Medical Association charges, plus whatever the brethren locally decide is necessary to carry on locally. We sincerely trust that our June Journal will carry the largest list of members the association has ever had."

The Medical Society of the State of New York does not publish a list of its members; but it indicates each member by means of a star prefixed to his name in the annual Directory which it publishes.

# MENSTRUAL AND CLIMACTERIC PAINS

For the relief of suffering during the menses it is desirable to administer a preparation that exerts an antispasmodic as well as an analgesic action. To allay the accompanying nervousness, a sedative is also indicated.

All these effects are combined in Compral. Excellent results from its use are reported in dysmenorrhea as well as climacteric disorders. Besides assuring prompt relief of discomfort, Compral enables patients to follow their occupations without drowsiness or depression. Painful uterine contractions after delivery also speedily subside under its administration.

Compral is equally serviceable in postoperative cases and other conditions where pain is a prominent feature, such as neuralgias, headache, migraine, gouty and rheumatic affections.

Dose: One or two tablets, according to the severity of pain, repeated three or four times daily.

Compral is supplied in tablets of 5 grains (tubes of 10 and bottles of 100)

#### THE OHIO STATE MEDICAL JOURNAL

The Annual report of the Officers and Committees of the Ohio State Medical Association are printed in the May issue of the Ohio State Medical Journal. The Publication Committee reports as follows:

"Every scientific manuscript is given thorough scrutiny and is carefully edited by the Publication Committee before it is approved for publication. The articles are not only judged from the standpoint of scientific value, but also as to literary style and general interest. A system of double editing is adhered to in order to minimize errors and obtain clarity and brevity. The committee has worked on the theory that every article appearing in The Journal, whether scientific or non-scientific, should be of a type which will add value to The Journal and be of information to the readers.

"In every issue of The Journal will be found numerous news notes concerning Ohio physicians, enabling members of the State Association to keep in touch with their colleagues in every part of the state. Activities in the hospital field also are recorded and considerable space is devoted to news of public health work and public health workers in Ohio and elsewhere. "A special section of The Journal is set aside each month for accounts of meetings of the component county medical societies and academies, and for advance notices of future gatherings of unusual interest. Secretaries of the various component county societies are urged to cooperate with the Publication Committee in its efforts to make this feature of The Journal one of outstanding importance.

"Governmental developments of importance to the medical profession and public health have been published, along with accounts of new regulations, interpretations and opinions promulgated or handed down by state and national departmental and judicial bodies on sub-

jects directly affecting physicians.

"The Publication Committee has tried to make The Journal an official, consecutive and permanent record of the new and outstanding developments in the field of scientific medicine; the activities of the medical profession in Ohio, individually and collectively, and a source of ready reference to the attitude and policies of the State Association toward the important and current problems and questions affecting medical practice and public health. The committee recommends that every mem-

(Continued on page 943-adv. xix)

(Continued from page 942-adv xviii)

ber keep a bound file of The Journal in his library as frequently references are made to articles and analyses in preceding issues.

"Every effort has been put forth to keep the advertising columns of The Journal above criticism. Many advertisements submitted to the Publication Committee are first turned over to the Cooperative Advertising Bureau of the American Medical Association or to the A.M.A Council on Pharmacy and Chemistry for censorship. Afterwards they are checked carefully and thoroughly by this committee. Advertisements with exaggerated claims for products are not accepted. All displays must be dignified in style and content. Because of this careful system of censorship, only reputable advertisers gain admission to The Journal. Therefore, they deserve the support and consideration of the readers."

#### COMMITTEE ON PUBLIC RELATIONS

The American Medical Association Bulletin of May contains the following appreciation of the Committee on Public Relations of New York State:

"The Medical Society of the State of New

York has a standing committee known as the Committee on Public Relations. Its report, in the New York State Journal of Medicine, May 1, 1930, indicates that this committee is doing a most important work and rendering valuable service in the interest of the society it represents and in the interest of the public. Helpful contacts have been established with official state agencies and with various lay organizations and groups that are concerned with public health and with other fields of medicine. Working with this committee are committees of a similar kind, with the same name, representing nearly all of the county medical societies in New York State.

"Committees on public relations are not new, but it is doubtful if the idea has been as fully developed in any other state as has been done in New York, where a hard working and efficient state committee has the support and active assistance of a similar group in nearly every county. The relations of organized medicine and the public are of profound importance and can be favorably influenced by the helpful activities of interested and intelligent committees that will study existing conditions and offer constructive suggestions for correction and improvement."

#### ORGANIZATION IMPROVEMENTS IN TENNESSEE STATE SOCIETY

The June issue of the Journal of the Tennessee State Medical Association contains an editorial suggesting some improvements in the State Association. The editor says:

"One cannot discuss all the changes that are needed in one short editorial, but it should be stated briefly that the Board of Trustees should be clothed with complete power to act on any matter between interim of the meeting of the House of Delegates.

"The House of Delegates should be reduced in size and really should meet on a day when the general meeting is not in session. For example, the House of Delegates at present is composed of the following groups: (1) elected delegates; (2) all officers; (3) ex-presidents in attendance.

"If all societies had been represented there would have been eighty elected delegates to the House. Add to this figure the number of officers, which includes councilors, vice-presidents, and then add the ex-presidents in attendance, and it is readily seen that the House may be composed of over one hundred delegates. The facts are that nothing like this number ever attend the session of the House. and further many of the delegates do not attend all the sessions of the House. There are a few delegates who attend every session. Besides these the House may be composed of an entirely different group each day, thus contributing to confusion, lack of understanding and lack of continuity of action.

It happened this year that matters were acted on one afternoon and the next day an entirely different group of men were in the House and the same matter acted on again. The first action was taken after full and free discussion. The second action was taken almost without discussion.

"The time consumed in the House has become so burdensome to members that good men often decline to qualify as delegates.

"Within the last two years there has been a wide divergence between two different committees in reference to the same matter.

"Complete authority should be vested in the House of Delegates composed as above suggested, then complete authority in the interim between the sessions of the House of Delegates should be vested in the Board of Trus-

#### **JOURNAL OF MISSOURI**

The annual report of the Committee on Publication of the Missouri State Medical Association, which is printed in the June Journal, describes the Journal as follows:

"The 26th volume of the Journal was completed with the December, 1929, issue. During the twelve months of that year the Journal printed 84 original articles and 25 articles under the Department of Washington University Clinics making a total of 109 original articles. There were 63 editorials, 63 obituaries, 159 reports of county societies, and the report of our Seventy-Second Annual Meeting, the report of the 53rd Annual Meeting of the Southeast Missouri Medical Association, and 14 reports of the Kansas City Academy of Medicine, and numerous miscellaneous items; 119 books were received for review and 88 reviews were published. These books were sent to the medical libraries of the St. Louis Medical Society, the Jackson County Medical Society, and some highly technical works to the medical library of the State University. The Journal contained 622 pages of reading matter and 502 pages of advertising, the latter earning \$9,868.62. The total expense including cost of illustrations was \$8,671.21, leaving a profit of \$1,253.21. The largest issue was for May, 1929, which contained 108 pages. The smallest issue was for April, 1929, which contained a total of 80 pages.

"Members are very generous in sending their contributions for publication so that the editor has sometimes found it difficult to publish papers promptly. There are at this writing 25 manuscripts awaiting publication."

## JOURNAL OF THE CALIFORNIA MEDICAL ASSOCIATION

California and Western Medicine is the organ of the three state medical societies of California, Nevada and Utah. It is one of the largest and most successful of all the State Journals, its June issue containing 88 pages of reading matter, 64 of advertising, and 4 pages of cover. The June issue also contains the minutes of the meeting of the House of Delegates of the California Medical Associa-

#### GRADUATE COURSE IN SOUTH CAROLINA

The graduate course under the auspices of the South Carolina Medical Association is described in the June Journal as follows:

"Some time ago the Secretary of the State Medical Association at the request of the Dean of the Medical College sent out a questionnaire to the physicians of South Carolina in an effort to learn just what interest there really is in post graduate education at the present time. Approximately one hundred and fifty physicians responded. Of this number about seventy-five stated that they would attend the course if offered at a convenient season. This large number greatly encouraged the faculty of the Medical School and it was decided to

put the course on again this summer. There are certain significant changes. Past experience seemed to indicate that the majority of practitioners were interested in medicine, pediatrics, obstetrics and clinico-pathological con-These subjects will therefore receive major attention. Past experience also seemed to show that the majority of medical men could and would leave their homes in considerable numbers and spend one whole week at the college, but not many would stay over for the full two weeks. It seemed wise therefore to concentrate on the above subjects and limit the time to one week. Now as we see it, it is the duty of the members of the State Medical Association to lend their full support to the Post-Graduate Course. Let us make our plans now to be open in Charleston promptly when the doors open. The full professorial staff will be our teachers. is an important point. In many summer courses elsewhere throughout the world, the heads of Departments are away on vacation. The Dean informs us this will not be the case in our State. The Association is keenly interested in adopting as a permanent policy some form of annual post graduate instruc-tion that will meet the need especially, of the general practitioners."

## New York Post-Graduate Medical School and Hospital

offers a four months' course in OPHTHALMOLOGY beginning October 1, 1930

The course includes: didactic lectures and practical consideration of diseases of the eye; anatomy, physiology, and pathology of the eye; refraction; operative ophthalmology on the cadaver; practical use of the ophthalmoscope and slit-lamp, etc. ¶ Under the direction of Dr. Martin Cohen. ¶ A large dispensary service in ophthalmology is available. ¶ Licensed physicians in good standing are admitted. ¶ A combined course in ophthalmology and oto-laryngology of 12 months may be obtained by following the above with an eight months' course in oto-laryngology beginning February 1, 1931.

For descriptive booklet and further information, address

THE DEAN, 302 East 20th Street, NEW YORK CITY

## CREST VIEW SANATORIUM

GREENWICH, CONN.

(20 Miles from Grand Concourse, or 25 Miles from Grand Central Station)

F. St. CLAIR HITCHCOCK, M.D., Proprietor

Elderly people especially catered to. Charmingly located, beautifully appointed; in the hilly country 1½ miles from L. I. Sound, where the air is tonic. Easy, quick drive from N. Y. City. Physician's cooperation invited on cases. Families who must travel leave invalid or elderly relatives with us in fullest confidence. Truly homelike; no institu-

tional appearance, beyond nurses' uniforms. Committments seldom necessary. (Disturbing cases, addicts, cancer and tuberculosis, are not desired.) Senile, infirm, gastrie, cardiac, post-paralytic, and invalid types accepted—besides mildly mental elderly. \$25-85 weekly. N. Y. office, 121 East 60th St. Tel.: Regent 8587; hours 11—1.

OR, TEL. 773 GREENWICH
Established 35 Years

A well known Urological Journal says:

"If you must use a diuretic, try the best —water"

This recommendation is well worthy of adoption especially

# Itoland Water

is used. ¶ Physicians have commented favorably on its bland diuretic properties for over 60 years.

#### POPULAR MEDICAL EDU-CATION IN FLORIDA

Dr. H. C. Dozier, of Ocala, Florida, in his Presidential address before the Florida Medical Association on May 6, at Pensacola, offered a plan for instituting popular medical education in the State. The May Journal of the Association, reporting his address, says:

"I wish to offer for your consideration the suggestion that this Association create a special 'Educational Committee' whose duties shall be specified, and whose activities shall be directed to medical education of the lavman and the doctor himself, if necessary; through a 'Speaker's Bureau,' for talks to various organizations, associations, clubs, etc.; a 'Radio' section, for work implied by its name; a 'Scientific Service Section' which shall prepare scientifically correct articles for publication through a 'Press Service,' or to be delivered over the radio, or read before organizations; and whose duty it shall also be to provide or secure films for use of lay groups or physicians. I would also suggest that this Association approve the same general plan for its component medical societies.

"I would like to see each medical society in this state either prepare or procure fifty-two articles each year, in advance, for publication in the local newspaper once each week, over the signature of the medical society, and not that of any member or officer. I assure you the ground is fallow, if we will only sow the seeds of education."

This address was referred to a committee of the House of Dele-

gates which reported:

"The Committee recommends that the suggestions of Dr. Dozier, as given in his address, be accepted by this Association, and be used as a guide in carrying out a five-year program of medical education for the laity.

"We recommend that the Executive Committee be made responsible for carrying out this program." HAY FEVER

# Lucous Membrane Inflammations

O-SILVOL is a valuable disinfectant in its specific field of treating mucous meminflammations without irritation. When the ethological factor is an infection ptococcus, pneumococcus, staphylococcus, or gonococcus—solutions of NEO-SILVOL we been found dependable in soothing the inflammatory process, in controlling growth bacteria, and in promoting a return to normal conditions.

NEO-SILVOL, a colloidal silver iodide compound, is effective without irritation. It does not precipitate tissue chlorides, or coagulate albumen, despite its antiseptic power. It leaves no disagreeable stains.

Select NEO-SILVOL for the treatment of any mucous membrane inflammation—in eye, ear, nose, throat, urethra or bladder.

#### How Neo-Silvol is Supplied:

In 1-ounce and 4-ounce bottles of the granules.

As a 5% ointment in 1-drachm tubes.

In 6-grain capsules, bottles of 50, for making solutions.

In the form of Vaginal Suppositories, 5%—boxes of 12.

Accepted for inclusion in N. N. R. by the Council on Pharmacy and Chemistry of the A. M. A.

# Dextri-Maltose for Modifying Lactic Acid Milk

In using lactic acid milk for feeding infants, physicians find Dextri-Maltose the carbohydrate of choices

To begin with, Dextri-Maltose is a bacteriologically clean product, unattractive to flies, dirt, etc. It is dry, and easy to measure accurately.

Moreover, Dextri-Maltose is prepared primarily for infant-feeding purposes by a natural diastatic action.

Finally, Dextri-Maltose is never advertised to the public but only to the physician, prescribed by him according to the individual requirements of each baby.

# Governed by the Same as Cow's Milk

When physicians are confrol with undependable fresh milk plies in feeding infants, it is well consider the use of reliable powde whole milks such as Mead's or well-known Klim brand. Such n is safe, of standard composition, a is easily reliquefied.

Under these conditions, Dexti Maltose is the physician's carbon drate of choice just as it is when fres cow's milk is employed.

The best method to follow is first to restore the powdered milk in the proportion of one ounce of milk to seven ounces of water, and then to proceed building up the formula as usual.

## THERE IS ONLY ONE -

The introduction of Antiphlogistine, more than thirty-five years ago, was the beginning of a movement in therapeutics for the modernization of the older methods of outward applications for the relief of congestion and inflammation. Antiphlogistine will do all that fomentation and poultices will do, and much more.

Over ordinary poultices it has

the great merit of cleanliness and asepticity.

To fomentations it is to be preferred, in that it need be applied only once in twelve hours.

The worldwide use of this topical application by the medical profession is evidence of its merit.

Write for sample and literature.

## A Dependable Agent For Supplying Calcium In Diffusible Form

KALAK WATER presents a saturated solution of calcium as the bicarbonate.

"Of the inorganic salts of calcium, the bicarbonate was the most effective in raising the blood calcium." (W. H. Jansen—Deut. Arch. f. klin Med. Oct. 1924.)

It is not possible to present calcium bicarbonate as a dry powder or as an effervescent mixture to be added to water. This salt can be maintained as the bicarbonate only in an aqueous solution that is charged with carbon dioxide.

KALAK WATER CO. 6 Church St. » New York City

# Expectant and Nursing Mothers

## Need this Food-Iron Concentrate

TRA demands are made upon the mother during pregnancy. The developing infant requires iron, not only for building up the blood which its body contains at birth, but, in addition, an equal amount to store up in its liver for use after birth.

The amount of spinach or other greens needed to supply the unusual iron requirement is too great to be eaten. without inconvenience, while the ordinary iron preparations available are not well utilized by the body in making hemoglobin.

Fortunately, however, these objections have been overcome by the introduction of a food-iron concentrate—

#### Food-Ferrin

In Food-Ferrin are found all the elements needed by the body for blood building. Under its use anemic animals recovered with remarkable rapidity, while ample clinical confirmation testifies to its value in actual practice.

Food-Ferrin is not a medicine, but a lighly efficient blood-building food. It is agreeable to taste, never disturbs but aids digestion, does not injure the teeth, and never causes constipation.

So that you can make a test of Food-Ferrin, we would like to send you a physicians' sample with our compliments. The coupon is for your convenience,

#### Arthritis, Sciatica, Lumbago, Neuritis and Gout. Exclusively

Painstaking diagnosis and therapy as indicated; complete clinical laboratory and department of physio-therapy.

SHANNON LODGE is the ideal place to which the New York phy-

sician may refer his chronic rheumatic cases. Located at Bernardsville, N. J., it is quickly reached over high-speed highways. The physician may maintain constant contact and control. Absolute quiet is assured by the 120-acre property. Buildings modern, thoroughly fire protected, beautifully furnished. Equipment is the latest and complete. The Medical Director is available at all times. Registered nurses, graduate technicians, trained masseurs and completely equipped metabolic and pathologic laboratories place every needed facility at the disposal of the referring physician. The rates are all inclusive and range from \$75 a week and up, depending upon the accommodations. Reservations are necessary. Admissions

selected. No mental, alcoholic or tuberculous cases admitted.

Realizing that many of the profession are too busy to come to Shannon Lodge to personally inspect its equipment and learn of its methods, we have prepared a special booklet for physicians. Please fill in and mail the coupon below so that we may send you a copy

SHANNON LODGE, Bernardsville, N J

Gentlemen
Please send me without obligation your booklet for physicians descriptive of Shannon Lodge and its methods

## Summer Diarrhea

Doctor

The following formula is submitted as a means of preparing suitable nourishment in intestinal disturbances of infants usually referred to as summer diarrhea:

# Mellin's Food . . 4 level tablespoonfuls Water (boiled, then cooled) . 16 fluidounces

This mixture contains proteins, carbohydrates and mineral salts in a form readily digestible and available for immediate assimilation.

The need for protein is well understood as is also the value of mineral salts, which play such an important part in all metabolic processes. Carbohydrates are a real necessity, for life cannot be long sustained on a carbohydrate-free diet. It should also be stated that the predominating carbohydrate in the above food mixture is maltose—which is particularly suitable in conditions where rapid assimilation is an outstanding factor.

Further details in relation to this subject and a supply of samples of Mellin's Food sent to physicians upon request.

#### What it is-

Serenium is a new, synthetic, organic, chemo-therapeutic agent which has the property of inhibiting growth of gonococci and staphylococci, when the drug is present in urine in a concentration as low as 1 to 15,000.

#### Indications\_

Serenium is indicated in the treatment of acute and chronic infections of the genito-urinary tract, especially those due to staphylococci and gonococci.

#### Advantages\_

Serenium offers many advantages.

- 1. Administered orally in the form of tablets—a welcome convenience to both practitioner and patient.
- 2. Preferable because of its low toxicity and high bacteriostatic power. Its presence in the urine inhibits the growth of the infecting organisms, thus limiting irritation and preventing the spread of the infection to new areas.
  - 3. Given in therapeutic dosages it

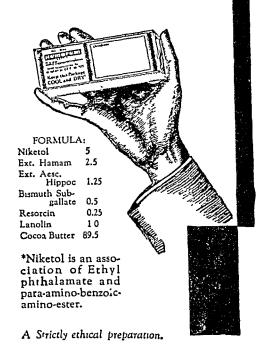

has no irritating effect on the kidneys.

4. It shortens the course of most genito-urinary infections and prevents complications. Clinical trials in leading hospitals and institutions have demonstrated its effectiveness.

#### How Marketed—

Serenium Tablets are marketed in bottles of 50 and 500.

#### MEDICINE UNDER SIEGE

By M L Harris, M D, President of the American Medical Association, Chicago, Ill Address before the Annual Meeting of the Middeal Society of the State of New York at Rochester N Y, June 2 1930

Y the word "Medicine" in "Medicine Under Siege," is meant the medical profession For ages the medical profession has been permitted to follow unhindered its humane oc cupation of caring for the sick, giving little heed to commercial and economic problems which were so foreign to its principles and to its traditions Of late, however, the world seems to have been given over to commercialism, and attempts are constantly being made to drag medicine from the humanitarian position of a sympathetic, hope-inspiring, sound medical adviser and to lower it to the level of a purely materialistic, commercial occupation, and would soon have it listed with the class of manual labor This may seem to be a pessimistic and extreme view of the situation but we think if one will devote a little study to the encroachments that are being made in the field of the practice of medicine to the attitude assumed by some of the great lead ers of industry as expressed in articles in popular lay magazines, to the dangers of misguided and misapplied philanthropy, to the extension of the work of health officers in the domain of the private physician, to the enactment by legislatures of arbitrary and unnecessary laws that place additional burdens on and restrict the independent action of the physician, we believe that one cannot fail to be impressed by the fact that the siege of medicine is on

#### Reducing the Cost of Medical Care

The purpose of a siege is to compel or coerce the besieged either by physical or moral means to surrender or to yield to the deminds of the besiegers. The object to be accomplished in the present instance, it seems to us, is to enforce a lowering or reduction of the cost of medical care. In the minds of the people the cost of medical care has been centered in the doctors' bills. Consequently these have been the target at which the propaganda has been aimed.

Whenever the people are aroused by a rather wide spread propaganda and become imbued with the idea that they are not getting what they are entitled to, they are wont to attack that which to their minds seems to offer least resistance and this often without stopping to analyze the situation in order to determine the cause of the disaffection or the effect of their attack.

#### Compensation for the Physician

The physician as a result of an ancient, cherished and hallowed tradition and the nature of his occupation, has always been of an altrustic turn of mind, and so far as his own material interests are concerned he has been labeled a pacifist in that he seldom if ever ofters resist ence to the encroachments being made in his own domain or field of activity. We need not discuss his particular field of action since it is well known and well defined. We think, however, that it will be acknowledged without equivocation that the services rendered by the physician are of an imperative or at least a highly desirable nature, therefore, the claim that he should be justly and reasonably compensated for his services needs no defense

#### Lines of Attack on the Medical Profession

It is probably owing to the particular traits and characteristics of the physician already mentioned that the siege has been laid on medicine. In laying the siege the usual plan is to so surround the besieged with the forces as to cut off their supplies. The siege may last a variable length of time. We are informed in a Greek legend that the Siege of Froy lasted ten years. The siege of medicine has been going on now for some time and the lines are gradually tightening, and unless something be done to break the siege the profession must suffer great loss. The forces engaged in this siege are quite numerous and likewise quite variable in kind. The profession has always

been possessed of the belief that the sick should have the best service that science is able to provide, and realizing how very important it is that every one who attempts to practice the art should be thoroughly grounded in the fundamental sciences pertaining to medicine—and medicine is the most comprehensible of all sciences—the profession has endeavored for years to elevate the standard of medical education and to encourage only those of scientific attainments and of the highest moral and ethical character to enter the profession. It would seem that every right-minded person would agree that this was the most approved way of insuring competent medical service for the sick at all times; but strange as it may appear, the people themselves have been the greatest obstacle to the consummation of this most laudable ambition of the profession.

#### Educational Requirements

Whenever the profession has aspired to induce legislatures to enact just and equitable regulations requiring that all who wish to treat the sick shall give evidence of possessing certain educational requirements, it has failed by reason of the enactment being defective or containing so many exceptions as to make it inoperative for the purpose desired, or to have the law overthrown by some court or judge on a mere technicality that is entirely beside the principle involved. It is owing to the failure of the people to act in this respect that permits the country to be overrun with uneducated and dishonest quacks and charlatans that prey on the ignorance and credulity of the sick.

It is claimed in this connection that the desire of the profession to have everyone who wishes to practice medicine possess a certain minimum educational requirement is but an attempt on the part of the profession to maintain a monopoly and that it is intolerant of cults and systems of practice other than its own, but science cannot be tolerant of ignorance, deception and superstition. Medicine is always conservative and requires that everything be submitted to the crucial test of science before being accepted, and demands that all else must do the same if it hopes to receive recognition.

## Legislative Attack on the Medical Profession

The law is taking quite an active part in this siege of medicine. There were introduced in the various legislative bodies during the past year 2500 Bills affecting the medical profession. Fortunately many of these bills that were fostered by the cults and which were intended to extend their rights and privileges were not passed. A number of them, however,

gave to osteopaths the same privilege accorded the regular profession. A number of bills favoring chiropractic, naturopathy, christian science, physiotherapy, sanatology, sanipractice, oralogy and drugless healing were introduced in several of the states; most of them, however, failed to pass. The number of these bills quite similar in character that are being introduced in the several states each year is constantly increasing. There seems to be a concerted action along this line all over the country and each year some gain in this respect is made.

If a man wishes to be an honest-to-goodness doctor with the kind of an education that one should have to entitle him to care for the sick and to command the respect and confidence of the people, it is not only necessary for him to spend several thousand dollars but also seven hard working years of his life in order to acquire an education that will permit him to apply for a license to practice. He must then pay a fee to the State Licensing Board for an examination and if successful in passing pay another fee for his license which will permit him to practice only in the state from which he receives the license. In addition to this in many states he will have to pay an annual registration fee to the state and an annual registration fee to the federal government for a license that will permit him to prescribe or give something to a patient to relieve his pain. Nor is this all. In some states an annual occupation tax is levied on practicing physicians. This is the door through which a scientific physician must pass before he is allowed to practice his calling, but if one without the necessary preliminary educational requirements that are imposed on the physician wishes to practice some so-called system or cultism of his own, the door is as open and easy to find as that of the average speakeasy in a prohibition town.

#### Burdensome Proposals

There have been many bills proposed in a number of the states imposing onerous duties on the physician such as to report in writing, wounds and defects coming to his attention, the names of patients who are infected with venereal disease and who fail to return for treatment. Minnesota enacted a law requiring the physician who attends or treats a child of pre-school age or of school age who is not attending school to report the same, also that any physician who observes any child in a family in which he attended or treats any patient, which child is suffering from any defect, injury or disease of a continuous nature, or which may handicap the child, to report the facts to the Department to which communicable diseases are required to be reported. A bill was introduced in Pennsylvania to require physicians to render services in any maternity

case when engaged at least three days prior to the confinement and to have a fixed fee for such services not to be varied between patients. A Georgia Bill proposed to limit the physician's fees in ordinary labor cases to \$15.00 and to make it a misdemeanor punishable by fine or imprisonment or both for a physician to refuse to attend any such case by reason of the compensation set out in the Bill. A bill was introduced in Ohio to require physicians and surgeons to file with the state board of health or the district health commissioner before performing any surgical operation a diagnosis of the disease or deformity for which an operation was to be performed. It seems scarcely possible that fanaticism could extend to such limits.

We believe that practically all will agree that the principle underlying workmen's compensation laws is right and that the costs of medical care for injuries arising out of and in the course of one's employment, including compensation for the injury, are legitimate charges on the industry, but we hold that the law exceeds its rights when it attempts to fix the physician's fees for the services rendered or the charges for hospital care so long as these are fair and just, depending on the nature of the services and the hospital care received. Nor do we believe there is any reason or justice in an opinion handed down by the Supreme Court of Massachusetts which said that when a man working under the Compensation Act is injured and taken to a hospital where he is cared for by a member of the hospital staff that the physician rendering the service is not entitled to compensation for his services since it is a part of the duties of a hospital to furnish medical and surgical care to its patients who have not called for or specified their own doctor. If such an opinion were to prevail it would be the height of injustice to the profession and could not endure.

The Insurance Companies and the Doctor

These are but a few of the activities displayed by a legal salient of the besieging forces. Closely allied with the legal forces, particularly the workman's compensation laws, are the casualty insurance companies that assume the financial obligations of the employers. These not only claim the right to have their own doctor take care of the injured but also the right to dictate the fees that any other doctor who may be taking care of the case shall charge for his services, but neither of these rights can he sustained. It is the policy of many of these insurance companies to make arrangement for the care of their patients with a hospital that will give them the lowest rates and these rates requested are often lower than the average per diem cost to the hospital. An endeavor is also made, and it has succeeded in some states, to have the rates that a hospital-may charge industrial cases, fixed by law. No hospital should make rates for this class of cases that are below the per diem cost nor should a hospital permit such cases to be entered as ward patients and assigned to members of the attending staff who are not allowed to charge for ward patients.

#### Free Clinics

We may next consider that very large group among the besiegers that may be called the charity workers. This constitutes a most important and steadily increasing group. There are something like over 5,000 clinics in this country, and it is estimated that 30,000,000 people availed themselves of the services of these clinics last year. Can it be possible that in this, the richest country in the world, where workmen receive the highest wages and the percentage of unemployment is the lowest, where the savings reach the fabulous sum of over \$19,000,000,000-I say is it possible that under such conditions about one-fourth of the population had to be treated in the clinics? Is it not surprising that such a large percentage of the people were unable to pay for their This very anomalous situation is due mainly to two causes-first, the inordinate propensity of the medical profession to bestow gratuitously its services whenever requested to do so, without attempting to analyze the situation to see whether the same are needed or even advisable, and second, the proverbial readiness of people to accept service whenever it can be had for nothing. It is astonishing the great amount of unnecessary charitable work by the establishment of out-departments of hospitals for the treatment of ambulatory patients, by teaching institutions conducting free clinics in all branches of medicine under the plea of the necessity of securing material with which to teach their students; by the establishment of governmental, municipal, public health and philanthropic free clinics, free inspection of school children, infant welfare stations, prenatal care of mothers, by the organization of hospitals and medical services by corporations such as railroads and industries, insurance companies, benevolent societies, group practice, by the creation of great foundations with almost unlimited means to provide medical services at reduced rates and in other ways,

The medical profession has stood alone in its readiness to contribute its services without compensation to many of theses projects. If it were necessary or desirable it would be done willingly but it is not. Charity is and always has been a dominant trait of the medical profession but it has no obligation, either

moral or ethical, to contribute its services gratuitously under ordinary circumstances to those who are able to pay something for them. It is unwise to force charity on people and there is great danger in too much misguided and misapplied philanthropy as it tends to make people improvident and thriftless and begets pauperism. It is particularly harmful in its ultimate effects when the government begins subsidizing state health departments or health agencies to encourage free services to those who are in need of them, such as is done by the Sheppard-Towner Bill.

#### The Health Department and the Physician

Public interest in health matters is increasing in an accelerating degree. Business men, the value and importance of health to the success of the business more than ever before. Federal, state and municipal governments are concerning themselves more and more with the health of the individual, realizing that the wealth and power of the nation depend upon that of its constituents, and that is why the field of operation of public health officers and health agencies are being constantly extended, even into the domain of the practicing physician. The work of the public health officer and that of the physician relate to the same general subject but there is a marked difference in their respective jurisdictions. The jurisdiction of the health officer is limited while that of the physician is unlimited. That of the former should be restricted to such matters of prevention of disease as concerns the community but should have nothing to do with the treatment of the individual, which is preeminently the province of the physician. The reason why so many public health officials overstep the bounds of their jurisdiction is due perhaps to the lack of interest which so many physicians take in enlightening their patients in preventative measures.

#### The Press and the Physician

The press, both dailies and periodicals, has opened its columns to the discussion of medical subjects, an opportunity usually taken advantage of by so-much-a-line writers, who draw unjustifiable deductions from limited knowledge of the matters discussed more with the idea of presenting sensational reading than of enlightening the public on the facts. The tenor of so many of these articles is so unfair as to give rise to the thought that they were intended to create in the minds of the readers a prejudice against all medical institutions and the honesty and good intentions of the physi-

As a good illustration of such an article the following is taken from a recent Sunday

edition of one of Chicago's leading newspapers: The article had a large page-wide headline-"What is Wrong with Our Hospitals." It was said to have been written by an intelligent observer (a woman who writes such articles for a living). Among other things it said—"The hospital pays no taxes; it has no bonds or stocks to pay dividends on; it does not need to earn or lay aside any funded debt or for depletion; the high-price surgeons and doctors cost the hospital nothing because they offer their work free in the charity wards and charge the private patients ample fees; some of the house staff of doctors work for nominal wages and the experience they get; the salary of superintendents and heads of departments are not enormous; many of the nurses are in trainemployers of labor, have become awakened to, ing and get little besides their board and experience; many of the workers around the wards are almost human derelicts paid very little in money and not much in food value; the cooks and kitchen help are the poorest paid variety. With no taxes to pay, with incomes from endowment funds and contributions from state, city and county, the hospitals are constantly passing the hat for individual contributions to make up deficits. While the hospitals give free service to the poor in the wards yet the private patients in the private rooms are made to pay amply for everything they get. From the moment a private patient arrives until he leaves, no service of any kind is rendered without being charged for. If a patient is sent in by his private doctor or surgeon he pays his doctor or his surgeon himself. If he has an operation he pays for everything that can be thought of in connection with it as for operating room service, for the anaesthetic, etc. If an analysis is made of the blood or of body fluids this is paid for at the regular commercial price. If an x-ray is taken the patient is charged at the regular rate of an outside laboratory. There is also a fee for the use of radium. If he has a private nurse the patient pays for her and her board. Until I became a hospital patient, I ignorantly supposed that hospitals were primarily for the care of the sick. But that is not so. They are primarily for the care of the equipment." This patient paid the munificent sum of three dollars a day for hospital care, nursing and medical service. The article ends with the statement that "seventy-five cents per head for food should be ample to defray the cost of wholesome food properly prepared and served in portions suitable to the requirements of an invalid. This leaves two dollars and a quarter a day per head for medical care, drugs, nursing, laundry and cleaning." The strange part of this is how any newspaper that hopes to have the respect of intelligent people could

print such an absurd and untruthful, if not malicious, article about hospitals and doctors

#### Mass Production in Medical Service

A new force has comparatively recently entered the besiegers, broadcasting the war cry of "mass production" Realizing that mass production has been the means of making a few men enormously wealthy and that it has resulted in reducing the cost to the people of the articles manufactured, these wealthy masters of the mills claim to have discovered a panacea for reducing the cost of medical care in what they are pleased to call "mass production" Just how mass production can be applied to the treatment of a sick person who is a distinct individual with reactions to disease and to treatment that is specific unto himself it is difficult for anyone to see but a pure business man who is engrossed in nothing but his own material affairs. But when we analyze the meaning of mass production as promulgated by these men we find it resolved into two ideas-1, lower cost and 2, one price to all In a recent article in a lay magazine, entitled "A Merchant Looks at Medicine," by one of these mass producers, it is stated that-"Un less there is one price to all, a business cannot organize for maximum service The healing business in other words is defrauded of any workable, economic check upon its activities It is held that medical care should be doled out in packages at so much a package, one price to all It is not surprising that these men of mass production who in their factories have reduced thousands of men to mere me chanical automatons should look upon them as so many puppets to be treated in a mechanical mass production manner But by enlightened physicians of humane instincts this cannot be done

#### State Medicine

From what has been said it is evident that the practice of medicine is under siege and that it is being encroached upon in a manner and to an extent that is affecting materially the welfare of the profession and it is essential that serious thought be given to these problems if disaster is to be averted But how is this siege of medicine to be raised? This is a question that concerns not only the profession of this country but also that of other civilized countries of the world We are all aware how compulsory insurance in Germany has about pauperized the general profession and has resulted in the country being overrun with practicing charlatans to a greater extent than almost any other country The situation has become very iccute in England The National Health Insurance system which has been in operation there for several years has not been entirely

satisfactory to the profession nor to the gov-The government has now introduced a Bill proposing to extend to all of the people, or to the entire population the present system of providing medical care at governmental expense to certain classes of the people This results practically in universal state med icine, or the socialization of the medical profession Medical care is to be served to all of the people and paid for by the government A physician is to be paid for his services by the government and naturally at a reduced The physician has thus become an employee of the state The profession repre sented by the British Medical Association, not being satisfied with the government's scheme has presented a proposal "for a general med ical service for the nation" The scheme presented by the Association is published quite in detail in the British Medical Journal of April 26, 1930

#### The British Plan

When the National Health Insurance Act was first proposed in England it was opposed strenuously by the British Medical Associa tion, but the political economists and the poli ticians succeeded in its becoming a law in spite of the opposition, and the medical profession had to yield to the inevitable. At that time compulsory health insurance in some form or other and so called state medicine became very live subjects for discussion in this country and some of the influential men of our own Asso ciation became proponents of the principles advocated, but fortunately for the welfare of the people and of the profession the agitation gradually subsided The health insurance system of England has survived and now that the labor party is in control in England it has been proposed to extend the national health act to make it universal in its application and to bring medical service to all classes of people This amounts practically to state medicine and if carried out would make the medical profession employees of the state. To ob viate this dire disaster, the medical profession has come forward with a plan of its own that proposes to provide the best medical care for all of the people and at the same time pre serve the independence of thought and action of the profession That the medical men of Ingland have been feeling a siege similar to that which we have just been relating as going on in this country is quite evident from the following quotation from Buzzard (Lancet, Oct 5 1929) "We cannot blind ourselves to the fact that the present position and reputition of the medical profession in the eyes of the pub-We cannot remain lie is unsatisfactory de if to the censure sometimes good natured sometimes ill natured, well founded or bise

less so frequently passed in ordinary conversation on doctors and doctoring. There can be little doubt that speaking generally we live in an atmosphere which may be described as unsympathetic and suspicious if not actually antagonistic." This expresses very clearly a feeling which seems to be growing in this country. That such a feeling must react disasterously on the people as well as on the profession is most certain. If the profession is wise it will act voluntarily and try to work out its own salvation without being coerced.

#### The Problem in the United States

The problem that has to be worked out in the United States is how to furnish the best medical service to all of the peaple all the time at prices within the means of all and without the overwhelming amount of unecessary charity that is now being given too lavishly by the profession. To begin with we must recognize that the present charity clinics do not satisfactorily solve the problem. About the only connection that physicians have with these clinics is to contribute their services without cost to the institution and to the great majority of the patients who are frequently able and should pay something for the service. In order to correct this great abuse it will be necessary for the physicians to own and conduct their own clinics.

#### Medical Centers Run by County Medical Societies

profession must organize, not we are organized today, simply for scientific purposes, but for business purposes as well. The general plan of organization of the profession is well established, and it is only necessary for each unit or county society to incorporate for business purposes and to add to its present duties that of looking after the material interests of its members. Each county society should then establish a medical center of its own, owned and managed by the society. This medical society should be the clinic of the community. What should constitute a community will naturally depend upon the size of the county or the number and size of the towns in the county, but as many centers as may be necessary to meet the needs of the people should be established. A center should consist of a suitable building or offices properly equipped for the diagnosis and treatment of all classes of cases. In other words, it is a clinic but not in the present sense of the free clinic but one in which all who receive services shall pay for them according to their economic The chief object of the center is to provide a place where those patients who are unable to have their own physician may receive the highest degree of medical care at a price within their means. There are many other advantages that these centers may bring to the physicians such as providing laboratory and x-ray facilities for its members, headquarters for society meetings, general library, etc. It is a common fear of physicians that such a center would be a great burden of expense to the society. On the contrary it would be a great source of income since everyone would pay something and experience shows that such a clinic properly managed would not only pay the expense of everhead and renewals but also earn something which could be used to help pay the physicians for their services. course, there are a few people so unfortunate as not to be able to pay anything, but such persons who are charges on the community would have to be paid for by the community at proper rates to be arranged for between the community and the center. Of course there would be a business head who with a superintendent and such other help as the size of the center would make necessary, would conduct the affairs of the center. The medical work naturally would be assigned to the doctors, the time and hours of service being arranged for in an equitable manner by the directors or trustees of the society. These centers, which would be established by the county medical society, would come under the general supervision of the state association and these in turn under the American Medical Association as in our present system of organization. The American Medical Association should encourage and foster the development of these centers all over the country. The numerous clinics that now exist for the free treatment of ambulatory patients would come under the control of the profession or else cease to exist; and the profession would then find itself master of its own business, something that is now rapidly passing into the hands of laymen.

The scheme would not interfere in any way with private practice, since those patients, who are able to pay the physician's rates will have their regular doctors as at present. The time which physicians are now giving gratuitously to the care of millions that are being treated in free dispensaries would be given to their own medical centers where all patients would pay for all services rendered in accordance with their ability and which would not only be of enormous financial gain to the profession but of inestimable value to the people by instilling in them self-respect and thrift and economy.

Let us act before we find ourselves in the same situation as our British confrères. Let us break the siege of medicine before it breaks us.

## A DISCUSSION OF UPPER ABDOMINAL PAIN' By EDWARD C REIFENSTEIN, MD., SYRACUSE, N Y

PPER abdominal pain may be a problem requiring the diagnostic skill of the internist and the surgeon. Mistakes in diagnosis have been made with serious and disastrous consequences. Unless careful consideration is given to all of the possibilities associated with upper abdominal pain, the diagnosis may be erroneous and the resulting therapeutic endeavor a failure.

Those in charge of hospital ward service can testify to the fact that it is not an uncommon experience to have patients, presenting acute upper abdominal symptoms, sent in for surgery in whom some non surgical, extra-abdominal lesion is found to explain the abdominal symp-Medical literature contains reports of such experiences where no pathology was found at operation, and a lesion, either in the chest, spine, or nervous system, was found at autopsy which would account for the abdominal symptoms Likewise patients are encountered in whom several laparotomies have been performed because of upper abdominal pain or discomfort, and in whom it is found that the complaint is referable to some serious cardiac or nervous system disease of this kind reflect upon the art and science of medicine

In recent years surgeons have tried to stress the importance of early surgery in acute upper They have tried to emabdominal lesions phasize the point that too much time should not be spent on differential diagnosis and that the operation should be done first and the This statement may be diagnosis made later accepted in those cases requiring immediate The doctrine has its limitations and is associated with certain dangers because it assumes that all upper abdominal pain and rigidity require surgery Unfortunately the surgical writers have failed to appreciate the fact that all the signs and symptoms of an acute abdomen may also be associated with the non-surgical extra abdominal disease

In the past the medical men were at fault for holding a case which required surgery too long, thus losing valuable time before calling a surgical consultant. It was natural that the surgeon should react to such a condition with the result that he felt it his duty to educate the profession relative to the importance of early surgical intervention in upper abdominal lesions. The medical profession and the internist have profited by such education.

But when one reads the discussions by surgeons upon the diagnosis of lesions associated

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Utica N Y, June 5, 1929

with upper abdominal pain, he rarely finds any reference to the possibility that abdominal pain may also be associated with extra abdominal At the present time it is encumbrant upon the internist to point out to the medical profession and to the surgeons that an acute upper abdomen must be appraised, not only as a possible intra-abdominal lesion requiring surgery, but also as a manifestation of an extraabdominal lesion in which surgery is not indi-It is therefore evident that these cases may assume borderline significance, and if errors in the diagnosis of the complaint are to be prevented, it is essential that there be a closer co operation between the medical men and the surgeons

While co operation is important in acute upper abdominal disease, it is frequently of equal importance in the patient with chronic upper abdominal distress in whom mistakes in diagnosis are made by both surgeon and internist. The case is sometimes treated by medical measures when surgery is indicated, and operations are sometimes performed when more study would have revealed that the condition did not require surgery. These errors in diagnosis are frequently due to hasty judgment and faulty interpretation resulting from incomplete clinical or laboratory evidence.

It is my purpose to discuss some phases of this problem and to present a few brief cast summaries illustrating some of the points. It will be helpful to consider that upper abdominal pain or distress may be a manifestation of two disease groups (1) the intra-abdominal group (2) the extra abdominal group

It has been my experience that the profession generally is familiar with the clinical picture of the various acute inflammatory conditions of the upper abdomen, whether it be from an acute cholecystitis, pancreatitis, biliary colic, perforated gastric or duodenal ulcer, or intestinal obstruction, and that it is cognizant of its responsibility associated with these various possibilities Its familiarity with these various disease conditions is no doubt due to the education which has been carried on by the surgeons However, in that group of patients in whom the complaint is one of upper abdominal distress without acute manifesta tions, the surgeons, the internists, and the medical profession soon realize their short-The relationship of comings in diagnosis upper abdominal discomfort whether acute or chronic to some intra abdominal disease, is not always easily established If the proper therapeutic agent is to be selected the various possibilities must be considered

In the extra-abdominal group of conditions, definite evidence of cardiac, pulmonary, or spinal disease; central nervous system disease; diseases of metabolism, and of the blood; and chronic nephritis may be found. In this group the manifestation of upper abdominal complaint may be either acute and serious or of a chronic discomfort. The internist can be of assistance in the detection of the diseases associated with this group. Just as the surgeon is familiar with the inside of the abdomen, so is the internist familiar with the different clinical pictures which this extra-abdominal group may present. It is therefore evident that a problem presenting so complex and bizarre a picture, and associated with so many possibilities, should require thought and consideration. All evidence should be carefully appraised and evaluated.

A carefully written history is the first essential in the differential diagnosis of upper abdominal complaints. A helpful and important history is not necessarily a lengthy history; in fact a few sentences may tell the whole story.

In writing the history it will be helpful to observe whether the patient is of the anxious, apprehensive type or of the phlegmatic type. The intelligence of the individual and his ability to accurately describe his complaint will be helpful. As the history continues valuable information may be secured concerning the patient's response to painful sensations. equal importance will be the knowledge of his environment, habits, and economic condition. Every endeavor should be made to obtain evidence of emotional disturbances; e.g., worries, anxieties, fears, disappointments, unhappiness, or an abnormal sexual life. These emotional upsets and conflicts adversely affect certain individuals so that marked disturbances of digestion or of cardiac physiology may result.

From these impressions and from the information secured from the patient valuable positive evidence may be obtained in favor of reflex conditions. These reflex conditions disturb function, and they should receive as much consideration as organic lesions. Neglect to appreciate the significance of this information or failure to obtain it, will explain some of the mistakes in the diagnosis of upper abdominal complaint as well as to explain the failure of surgery to relieve the discomfort.

The discomfort or pain may be mild or severe. From the intensity of the sensation alone one cannot evaluate the gravity of the situation. It is important to appreciate that a mild sensation in a certain type of individual may be associated with a serious intra- or extra-abdominal condition, whereas the complaint of a very intense discomfort or pain in another

type of an individual may be found upon careful analysis, to be without any serious intraor extra-abdominal disease. An aching sensation in an ignorant negro may be associated with a more serious condition than a complaint of an acute intense pain in a school teacher of high intelligence, in whom there is a certain type of a nervous system.

If the complaint is acute, only the essential points in the history should be obtained. The presence of previous indigestion has significance, especially that type associated with periodic attacks of discomfort, periods of freedom from the discomfort, and relief by food and alkalies. A direct question will usually bring a satisfactory answer and will indicate the possibility of ulcer, the perforation of which may explain the picture. Previous operations may explain an acute attack of intestinal obstruction due to adhesions. A history of biliary colic in a case of intestinal obstruction, may find explanation in the passage of a gall stone through the intestinal tract.

If one obtains evidence of epigastric or substernal discomfort or pain, especially in a male, associated with or without pain in the face or arms, and occurring with exercise, emotion, or excitement, and relieved by rest, it is valuable evidence and should immediately suggest coronary disease. The complaint may be only one of pressure occurring with exertion after meals, and it is then often erroneously interpreted as gas because of belching associated with rest.

If this evidence is obtained in a patient pre senting the signs of an acute abdomen—e.g. nausea, vomiting, abdominal pain, tenderness and rigidity, cardiac infarction must be ruled out before surgery is considered. Other signs of this condition such as moisture at the bases, evidence of collapse, a fall in blood pressure, or a friction rub over the heart, may then be found. There is usually a history of hypertension of many years' duration which evidence should also suggest vascular disease.

The history of dyspnoea on exertion with occasional attacks of nocturnal dyspnoea, indicates the possibility of a myocardial condition. Recurrent epistaxis, attacks of rheumatic fever, or hemoptysis followed in later years by shortness of breath, and irregular heart action, suggest the possibility of broken compensation associated with mitral stenosis. The right heart failure will account for the acute abdomen in these conditions, by causing congestion and tenderness of the liver. The history of a recent attack of acute polyarthritis is helpful and may suggest an acute rheumatic pericarditis as an extra-abdominal lesion associated with intense epigastric pain. The history may reveal recurrent attacks of tachycardia. A sudden transition in the rhythm or rate of the heart may be associated with sudden enlargement of the liver with resulting signs of upper abdominal pain and rigidity. The rapidly beating heart may be the cause of the condition and not a sign of peritoritis, as some surgeons believe

Discomfort in the epigastrium after meals, occurring in a female who also gives a history of having had several attacks of severe pain in the abdomen, usually occurring at night and relieved either by a hypodermic or hot drinks, puts the responsibility of the presence or absence of gall bladder disease upon the physician history of the removal of a tumor of the kidney in which hematuria was present and which was later followed by severe upper abdominal pain with jaundice, will indicate the possibility of a metastatic disease affecting the liver The history of an operation for the removal of a tumor of the breast which, in a few years is followed by severe paroxysmal epigastric pain, usually worse at night and frequently increased by a change in position, arouses the suspicion of metastatic disease of the spine or the cord

The history of severe pain in the upper abdomen in which the pain is aggravated by change in position, will suggest some arthritic change of the spine The patient is frequently awakened at night by severe paroxysms of During the height of the paroxysm the abdominal muscles are tense, rigid and tender The patient finds difficulty in turning from side to side and holds himself rigid. He also complains of severe pain in the back as well as in the abdomen If this condition should follow a case of typhoid fever, spondylitis should be considered. In two cases it was my experience to have seen an osteomyelitis of a rib associated with spinal difficulty. A culture from the abscess of the rib revealed a pure culture of typhoid bacilli

The story of polyuria with excessive thirst and the presence of sugar in the urine for some time, followed by a sudden acute attack of upper abdominal pain, collapse and prostration, suggests the possibility of acute pancreatitis

The female seeking relief from upper abdominal discomfort, with a history of frequent operations, is familiar to all of you. You are soon impressed with her anxiety as to the nature of the discomfort as well as the anxiety over the presence and significance of mucus in the stools. She describes frequent attacks of pain in different parts of the body. She suffers from recurrent attacks of headache. She usually has one or more scars on the abdomen as a result of previous operations. While this individual is usually thin and emaciated, nevertheless it is important to recognize the fact that

over-weight and well nourished individuals are sometimes affected. When operations are performed upon individuals with this history, it usually is because the indications for operation are based upon incomplete and improperly evaluated histories. The history is character istic. It is usually lengthy requiring considerable time and patience to obtain it.

The evidence from the physical examination is important. It is often valuable and may establish the diagnosis. The appearance of the patient is important. The ashen color of the patient suffering from coronary thrombosis striking. The malar flush and the cyanosis associated with initial disease, attract attention. The flushed face with the playing alaenasi is significant of acute pulmonary disease.

The posture in bed which the patient as sumes, may be of considerable diagnostic importance. The contrast between the appearance of the patient with an acute cardiac condition, propped up in bed, and the one suffering from acute peritomits where the thighs are flexed on the abdomen, is striking

In acute pulmonary disease the patient fre quently lies on the affected side. The patient with spondylitis holds himself rigid ever he attempts to move, it is observed that his entire body moves as if he were in a The character of the respiration plaster cast whether thoracic or abdominal should be appreciated. In the examination of the chest for the detection of acute pulmonary disease search should be made for impaired resonance, diminished breath sounds, increased whispered voice sounds, and moisture at the bases of the lungs These signs in the chest may account for the abdominal manifestations associated with acute pulmonary disease

If acute cardiac infarction is suspected, the lungs should be carefully examined for evidence of moisture at the bases and a pericardial friction rub searched for. These signs are of diagnostic importance in the early diagnosis of coronary thrombosis. If a decided fall in the blood pressure has occurred, it will be valuable additional evidence. Careful attention should be directed to the intensity, quality, rate, and rhythm of the heart sounds the examination for the pericardial friction rub of rheumatic fever, it may be necessary to have the patient bend forward in order that this sign may be detected. If the apex beat is found displaced upward, and if dullness and bronchial breathing are found at the left base then the possibility of an acute pericarditis with eitusion associated with the acute abdominal symptoms, should be considered

Physicians should be familiar with the fict that a sudden transition in the curdiac rate or rhythm may be associated with reute ab dominal symptoms which may appear alarming and dangerous. The sudden onset of paroxysmal auricular tachycardia, auricular flutter, or auricular fibrillation, may be associated with a dilated right heart and an enlarged tender liver. Persistent auricular fibrillation may be associated with an engorged liver which may account for a chronic upper abdominal complaint. It is essential that a physician be familiar with the diagnostic criteria which will enable him to identify the nature of the various disturbances of cardiac rate and cardiac rhythm. His ability to recognize the type of disturbance may result in a very dramatic therapeutic result.

Careful examination for evidence of mitral stenosis should be made. Attention should be directed to the presence of the characteristic mid diastolic murmur. For the detection of the murmur it is essential that the examination be made when the patient is in the left lateral position. If such evidence is found it may be a diagnostic aid in favor of an acute abdomen due to an enlarged tender liver associated with a dilated right ventricle. A diastolic murmur heard over the aortic area, along the left border of the sternum, or at the apex may suggest syphilis. An accentuated aortic second sound with a metallic ring, in the absence of hypertension, may also suggest further investigation for syphilis. Syphilis of: the central nervous system may explain obscure upper abdominal discomfort. The presence of hypertension should direct attention to the vascular system. The ophthalmoscopic examination of the eyes may reveal valuable evidence of vascular disease.

In the examination of the abdomen it is important to note the type of respiration, the presence of localized spasm, rigidity, or tenderness, and the presence of a palpable mass. The presence of cutaneous hyperesthesia may suggest a lesion above the diaphragm. It is important to observe whether a change in the position of the patient aggravates the pain in the abdomen. If so, careful palpation of the spine for evidence of tenderness should be made. As a rule the discomfort in this type of a case is of a chronic nature and will require a detailed examination of the spine for evidence of motility and fixation. A physician should be familiar with the fact that radiculitis may be associated with severe abdominal pain.

The examination of the nervous system should be complete. The reaction of the patient to sensation and to the presence of painful and tender areas should be determined. It will not be sufficient to test only the condition of the patella reflex, but attention should also be given to the achilles reflex. It is often the first reflex which will be found diminished or absent in syphilis of the nervous system. The examination of the vibratory sensation will be helpful. If it is found

to be diminished or absent, it will be a valuable confirmatory sign of spinal cord disease.

The other points in the physical examination which should be studied are: the condition of the mammary glands and pelvic organs in the female; the condition of the prostate gland in the male; and the condition of the glandular system and the skin.

Laboratory Evidence.—Certain laboratory observations are of valuable aid in the diagnosis. It is true that the laboratory evidence is often improperly evaluated. Those in charge of the Roentgen Ray and chemical laboratories can testify to the fact that many requests are made for studies and observations with the result that extensive laboratory investigations are carried out. In many instances these tests are made without the physician having the least impression or lead as to what the patient's condition is or the particular reason for doing the laboratory work.

In the minds of certain practitioners this constitutes a complete investigation, and they hope that these laboratory tests will prove to be a short cut to the correct diagnosis. In other words, they hope to "let the other fellow do it." It is often true that the more laboratory work requested, the more likely it is that the keystone of the case is missing. The keystone in the medical diagnosis is the clinical history. Without it the diagnostic structure can not be built. The more accurate the history is, the less extensive will be the laboratory invesigations required.

Nevertheless the laboratory is an essential aid in the diagnosis of certain conditions. especially true in the chronic type of discomfort or the recurrent attacks of discomfort. The gall bladder visualization test if properly done and properly interpreted, is a helpful aid in diagnosis. Questionable evidence should not be allowed to appear in the final appraisal. It is more likely to mislead than to be of aid. Whenever there is a reasonable doubt as to the significance of this evidence, it had better be omitted. Additional evidence of gall bladder disease may be the indirect signs of it which are found by means of a barium series of the gastro-intestinal tract. Careful roentgenograms of the spine taken in different positions with careful interpretations by a competent roentgenologist have distinct value.

The electrocardiogram will give valuable information in certain cases. This is especially true in the male in whom there is a complaint of upper abdominal discomfort, and coronary disease is being considered. If there is positive evidence of an abnormal electrocardiogram, e.g., inverted T wave, low voltage, prolonged Q-R-S interval, all of which indicate disturbance of the electrical conduction through the heart, then this evidence should not be ignored, but should be carefully evaluated and appraised for it indicates some change in the heart muscle. It is sometimes difficult to establish the relationship of an abnormal

electrocardiogram to the present complaint. Careful consideration of all the evidence is essential. It is important to appreciate that there may be myocardial or coronary disease present with a normal electrocardiogram. However, an abnormal electrocardiogram reveals definite evidence of some damage to the myocardium at some time.

No patient, especially a male around fifty years of age, with an upper abdominal complaint, whether this complaint be a mere discomfort or a severe pain, has been properly studied unless an electrocardiogram has been made. This is especially true in the ambulatory type of a patient who comes to us with indefinite sensations which he calls "gas." Gas is a self-made diagnosis which causes me considerable difficulty in evaluating. It is often extremely difficult to find out just what is meant by gas. It is sometimes described as pressure, or it is called "gas" because relief from the discomfort is obtained either by taking soda or from belching. It is important to consider that "gas" trouble is but a mirror and that the real image is often found in the disturbance of the coronary system. It is then that the electrocardiogram may be helpful.

In acute upper abdominal pain the blood examination may be an aid. However, too much dependence should not be placed upon a leucocytosis in favor of inflammation, because a leucocytosis also occurs with acute cardiac and acute pulmonary infarction. The spinal tap may bring the deciding evidence with positive serological findings in a case of obscure chronic upper abdominal discomfort. Chemical blood studies may have evidence of limited value. The study of the urine should always be made and cellular elements properly evaluated with the clinical pic-

ture.

An abnormal electrocardiogram or cholecystogram, or careful roentgen ray studies of the chest, spine or gastro-intestinal tract, may reveal valuable information. Careful studies of gastric acidity and motility may be helpful. These laboratory tests may furnish valuable information as well as the necessary diagnostic link in the chain of evidence. It is essential that the proper interpretation of all laboratory evidence be made in the final appraisal. Repeated laboratory tests have greater significance and value than one test. All laboratory evidence of doubtful or questionable value will justify the repetition of the test, or else the evidence should not influence the final opinion.

#### Conclusion

You will then realize that upper abdominal pain or discomfort may be a difficult problem. In order that mistakes in diagnosis and treatment may be prevented, it is important for internists and surgeons to appreciate that an acute upper abdomen may be a manifestation of an intra- or extra-abdominal disease. Surgery should not be

attempted until all the possibilities associated with these disease groups have been considered.

It is evident that the most important diagnostic aid in this problem is the history. In acute cases only very essential points should be secured, whereas in a chronic complaint a more detailed, time-consuming history may be necessary in order that the correct evidence may be obtained. The physician and surgeon must realize that severe upper abdominal symptoms may be associated with emotional upsets as well as with organic disease.

Another essential aid in arriving at the correct diagnosis is a complete physical examination. Positive signs may establish the diagnosis. Emphasis upon abnormal signs without regard to their significance and their relation to the complaint, may be harmful. The absence of abnormal physical signs may be as helpful as their presence in the final appraisal of the evidence.

The history and the physical examination should indicate the necessary laboratory aids which are required. This evidence when properly obtained and properly interpreted may be of distinct value in arriving at the correct diagnosis. Finally it is essential that the physician have the proper state of mind in approaching this problem with the chief object and desire being to relieve the suffering of an individual. This he can best do by first attempting to make a satisfactory diagnosis. In order to do this it will be absolutely necessary that he consider all the various possibilities associated with the condition and not to arrive at a hasty conclusion. After this has been done he should give the same careful attention to the therapeutic indications of the case.

In my opinion, if this manner of approach is followed more accurate diagnoses of upper abdominal complaints will be made, resulting in more satisfactory therapeutic responses.

Case No. 1, No. 4555, male, age 55 years—Seen in consultation on May 1, 1928, because of severe epigastric pain. Ten years previously had had attacks of polyarthritis. Attack of pain occurred suddenly. Ten one-quarter grain codeine tablets prescribed without 'relief. Pain paroxysmal and stabbing in character.

Examination—Patient sitting up in bed, bending somewhat forward. Located the pain in upper epigastric region and lower left chest. Temperature 99.8, pulse 104, respiration 40.

In upright position definite to and fro friction rub heard over the precordium. Forcible first sound. No murmurs. Apex difficult to locate. Dullness at left base with diminished breath sounds.

In the prone position patient has paroxysms of severe pain at which time he places his hand over epigrastric region. Examination reveals tense, rigid abdomen. Pain controlled by morphine and saheylates

Examination following day—temperature 104, pulse 120, respiration 44. Face flushed. Heart sounds of diminished intensity. Increased dullness at left base with bronchial breathing.

Diagnosis-Acute pericarditis with effusion.

Case No. 2, No. 2403, male, age 55 years— Tumor of right kidney removed on February 4, 1922. Pathological examination—hypernephroma.

Convalescence uneventful.

Seven weeks later suddenly seized with severe pain in epigastric region without vomiting. Followed by generalized pain throughout the upper abdomen and associated with light colored stools.

Examination—Rigid and tender upper abdomen. Enlargement of liver, jaundice, emaciation.

Following this attack, jaundice increased in severity, followed by nausea and vomiting. Generalized pains in different joints with weakness and later evidence of sensory aphasia. Four months later death following general exhaustion.

Autopsy—Metastatic hypernephroma of lungs, intestinal wall, liver. Tumor of inferior vena cava. Infarction of brain, medulla, spinal cord.

Case No. 3, No. 3524, male, age 73 years—Began eight days previously with severe pain in epigastric region requiring opiates. Pain associated with vomiting.

Eight hours later temperature 101. Definite epigastric tenderness and rigid abdomen. Surgeon called. Diagnosis: Cholecystitis. Temperature continued for seven days.

On the morning of the eighth day another attack of severe epigastric pain located beneath the ensiform cartilage with abdominal rigidity and marked dyspnoea and cyanosis.

Examination—Ashen-slate color of skin, cyanosis of lips and fingers, marked dyspnoea. Heart sounds distant and feeble. Gallop rhythm. Blood pressure 86/60. Moisture at both bases. Liver edge hand's breadth below the costal margin. The following day sudden death.

Diagnosis—Coronary thrombosis. Cardiac infarction.

Case No. 4, No. 3217, male, age 47 years—Chief Complaint—Discomfort in epigastric region of three years' duration. Had been studied by internist. Roentgenogram studies made of the gastro-intestinal tract. Diagnosis—Chronic appendicitis. At operation appendix found thickened. Gall bladder normal. No relief following operation. Discomfort in epigastrium persisted. Aggravated by food.

Additional history—For three years had been conscious of pain in mid dorsal region. Increased when getting out of bed or bending forward. At the time of operation six months previously x-rays of spine reported negative. Six months later x-rays of spine reported—Evidence of hypertrophic arthritis.

Improvement in abdominal symptoms with fixation of spine.

Case No. 5, No. 2606, male, age 40 years—Seen because of severe pain in upper abdomen and in dorsal—lumbar region. Paroxysmal in character. Four months previously had had severe attack of typhoid fever with hemorrhages. Two months later osteomyelitis of rib.

Physical examination—Tenderness of first lumbar vertebra. Increased pain when patient attempts to move. Abdomen rigid and tender during the paroxysms of pain. Nausea and vomiting also present. Temperature 99, pulse 80. X-rays showed destruction of twelfth dorsal and first lumbar vertebrae.

The application of a plaster cast to the body and the administration of typhoid vaccine relieved the condition.

Case No. 6, male, age 40 years—Was admitted to the University Hospital as a private patient for an acute surgical abdomen. For four days had had severe epigastric pain, nausea, and vomiting. The abdomen was rigid and tender!

Preparations for operation were made when an internist discovered evidence of cardiac hypertrophy, aupricular fibrillation, and hypertension, with a palpable liver edge, 5 cm. below the costal margin.

Digitalis therapy changed the entire picture

within twenty-four hours.

Case No. 7, male, laborer, age 38 years—Admitted to University Hospital October 20, 1926, because of pain in epigastrium of nine days' duration. Progress stationary. Past history unimportant.

Present Illness—Began on October 11, 1926, while in bed with aching in epigastric region associated with belching of gas. No other symptoms except slight dysphagia. No change for eight days. When admitted had very slight epigastric pain of aching character. No vomiting. Temperature 101, pulse 80.

Physical Examination — Essentially negative except slight tenderness on deep pressure in midepigastrium. Blood count, whites 19,000, polys 81%. Repeated blood cultures and widals negative. Examination of feces negative. Temperature continued. No new complaints.

No change in patient's condition for six days. Then chill, rapid respiration, cyanosis, temperature 105. No localizing signs. Leucocytosis continued. Blood culture negative. Two days later exquisite tenderness in epigastrium with rigidity. Surgical consultant advised observation.

Three days later operated. Liver found enlarged to the left, purple color. Manipulation followed by sudden appearance of pus from its under surface. Patient expired following day.

Autopsy—Liver weighed 3300 grs. Two large abscess cavities in left lobe, each 10 cm. in diameter containing gray purulent material. No amoebae recognized.

## HAY FEVER; ITS SYMPTOMATOLOGY

### STUDIES IN HAY FEVER IV\*

By A A THOMMEN, MD, NEW YORK, NY

Introductory The term hay fover appears to have originated among the laity shortly after Bostock first described the disease in 1819, when hay was regarded by many as the cause, and when the term fever was loosely applied to many indispositions, without recourse to the chinical thermometer synonyms have been in use, some based on the supposed cause-Rose Cold, Pollen Catarrh, Ragweed Fever, Corizza da Fieno, Rhume des Foms, others relate to the particular season of incidence-Summer Catarili, June Cold, Autumnal Catarrh, Fruhsommer-Katarrh, and others again are associated with the symptoms-Rhinitis Pruritus, Spasmodic Rhino-bron chitis, Niesfieber In Germany it has also been called Bostock'scher Katarrh, and in France Asthme hav des Anglais

As a determinative name, hav fever is a mis nomer, for the malady is neither due to hay nor characterized by any definite rise in temperature A more satisfactory term is pollinosis It is well, however, not to be too critical of the etymological significance of medical terminology Many terms do not bear too rigid an analysis, eg melancholia, hypochondria vitamine tularaemia, yet their serviceableness is undisputed, particularly if it be borne in mind that the function of any name, as of language in general, is the adequate conveyance of an idea or concept. The term hav fever is now universally in use to designate the train of symptoms induced in specifically sensitive individuals through the adequate contact with specific pollens It has been given a generic significance so that we speak of tree hay fever (or tree pollen hay fever), grass hay fever and weed hay fever It quite probably has attained a permanent place in medical nomenclature

The term hav asthma has been used to designate the asthma which is caused by pollen, and is correlative with such terms as cat asthma, horse asthma, etc. It, too, is unsatisfactory, a more correct designation being pollen asthma (The reader is referred to a previous paper for a complete discussion of the etiologic significance of pollen.)

The symptoms of hay fever vary greatly in different individuals, with regard to the time and mode of onset, the comparative intensity of the various local manifestations, the tendency to bronchial involvement, as well as their general severity and duration. In general, the symptoms result from an acute inflammation of the more readily accessible mucous membranes—the ocular, nasal, buccal, pharyngeal, eustachian and bronchial. Occasionally one observes certain cutaneous manifestations, irritations of the skin of the face and nick, a specific dermatitis, urticaria and eczema. The symptoms are similar in the three forms—tree, grass and weed hay fever.

I his is usually gradual, though The Onset not infrequently it is quite sudden. The initial symptoms are those of a mild sensation of itching and burning at the inner canthi, or a similar sense of irritation felt within the nasal cavity, the fauces, the palate or nasopharynx These are, as a rule, entirely subjective and may be viewed as being precursory or prodrom-The gradual onset is due to the occurrence of the gradually increasing quantity in the atmosphere of the offending pollens At times, the onset is sudden-that is to say, the symptoms reach their maximum development within a few minutes This type of onset results from the patient being suddenly exposed to a mass of pollen, as, for example when passing through a field containing numerous offending plants in the early pollinating stage symptoms may be divided into two groupsthe catarrhal symptoms ie the oculo nasalpharyngeal, etc., and the asthmatic symptoms

The Catarihal Symptoms The Nose initial stage of irritation which may last from several hours to a few days, is followed by certain nasal and ocular manifestations Soon. there is developed a sense of pressure at the bridge of the nose and a feeling of fulness within the misal cavity, which invariably presages the obstruction of nasal breathing because of the swollen mucosa, and which is usually accompanied by paroxysms of sneezing and a profuse watery discharge The sneeze is rarely single, but generally occurs in pro-longed, violent paroxysmal seizures in which sternutation occurs 10, 20 and even 50 times in rapid succession, frequently leaving the patient quite exhausted, in a profuse cold perspi-The threshold of excitability of the sneeze reflex is greatly lowered in the hay fever subject during the period of illness, so that though the chief cause of the sneezing paroxysms is the specific excitant of the offending pollen, the excitability of the sensitive nerves of the nasal passages is so intensified that sternutation is induced by a variety of

Thommen A A. The Enology of Hay Fever Studies in Hay Fever I New York State Jour of Met. April 15, 1930

ordinarily innocuous substances and circumstances.

"Your handkerchief suddenly becomes the most important object in life. By the next day the slightest draught or wind sets you to sneezing. It is a revelation. You never before even suspected what it really was to sneeze. If the door is open you sneeze. If a pane of glass is gone, you sneeze. If you look into the sunshine, you sneeze. If a little dust rises from the carpet, or the odor of flowers is wafted to you, or smell of smoke, you incontinently sneeze. If you sneeze once, you sneeze twenty times. It is a riot of sneezes. First, a single one like a leader in a flock of sheep bolts over and then, in spite of all you can do, the whole flock, fifty by count, come dashing over, in twos, in fives, in bunches of twenty."—(Henry Ward Beecher.)

The sneezing is almost invariably accompanied by a profuse watery discharge from the nose which may be so copious as to require the use of several dozen handkerchiefs daily; and yet, is at first so clear as to be almost stainless. As a result of the paroxysmal sneezing and rhinorrhoea the nasal obstruction is lessened, and the patient breathes somewhat more freely-a condition which is all too soon followed by another attack. These attacks may occur throughout the day, but are more severe at certain hours, for example on first arising in the morning when the circulation responds to a change of position and the surface of the body, particularly the extremities, is subjected to a change of external temperature. The variation in intensity of the various symptoms is due primarily, however, to the greater content of pollen in the atmosphere at various periods during the day. The ragweeds and many of the grasses shed their pollen chiefly from some time after sunrise to about

The Eyes. Coincident with, or immediately following the nasal symptoms, the itching of the inner canthus progresses along the edge of the lids and spreads to the conjunctiva generally, there being manifest a more or less marked congestion of the conjunctival and ciliary vessels associated with a profuse lachrymation and a variable amount of photophobia. The ophthalmic symptoms like the nasal, also occur in paroxysms of varying duration, but owing to the almost irresistible impulse to relieve the itching and burning, by rubbing, which serves but to intensify the irritation, the eyes soon take on the appearance of chronic inflammation. In severe cases, chemosis and ædema of the lids may occur. The complaint that the eyes feel as though hot sand or dust were in them is quite common. In addition to the burning and itching of the eyes, many patients complain of pain within the eyeballs, of constriction above the eyes, and of frontal headaches. Vision is practically unimpaired, tho the writer has seen two cases of doublevision which occurred annually, limited to the period of the hay fever symptoms.

The Mouth, Pharynx, etc.: As the disease progresses, the symptoms become more intense and the areas involved more extensive. The mucous membranes of the mouth (almost solely the hard and soft palate), fauces and pharynx become inflamed, and in many instances the inflammatory process extends into the eustachian tube. The uvula is often greatly inflamed and very ædematous. Thus are occasioned the repeated, painful swallowing movements, the disphagia and the irritative, hacking non-productive cough. The obstruction to nasal breathing described above results in mouth breathing for fairly long periods, and serves to aggravate the mouth and throat symptoms. Itching, almost intolerable in character, is commonly complained of at the roof of the mouth, and within the head or earthat is, in the eustachian tube, where, because it is inaccessible to the temporary relief afforded by scratching, it is all the more distressing. Tinnitis and impaired hearing are often associated.

Frequently, the nasal secretions, quite watery and transparent, at first, become thick, opaque and muco-purulent, and in the more severe cases produce excoriations about the tip of the nose and upper lip, associated with redness in the region of the alae. A similar change occurs in the lachrymal and conjunctival secretions, giving rise to the disagreeable adhesive condition of the eyelids, particularly in evidence when the patient awakens in the morning. In some severe cases the entire face appears swollen.

The Skin: Generalized erythema, dermatitis venenata, urticaria and eczema are sometimes observed as phases of the hay fever symptomatology. They are, however, uncommon manifestations.

Illustrative case. Male, aged 36, several of whose direct and collateral antecedents had hay fever and asthma, suddenly developed a severe attack of hay fever one morning (August 20th) whilst passing through a field of an almost pure stand of ragweed, in an endeavor to make a so-called short cut. On entering the field the patient was immediately seized with a paroxysm of sneezing. When he had progressed to the middle he experienced such severe asthmatic symptoms, that it was with great difficulty that he arrived at the other side of the field. His return home was accomplished with even greater difficulty. When seen about two hours after, it was noted that in addition to the moderately severe catarrhal and asthmatic symptoms, there was a generalized scarletiniform erythema; and areas of urticaria on the back and abdomen. Adrenalin proved quite effective. The diagnosis of ragweed pollinosis was subsequently established and phylactic treatment instituted.

The variation in the pollen content of the air and its relation to the various meteorological phenomena, will be discussed in detail in a forthcoming paper.

On at least three other occasions during that season the patient had attacks of crythenia and urticaria associated with severe attacks of the ordinary hay fever symptoms

During the past three seasons, a satisfactory response to the prophylactic and seasonal treatment with rigweed pollen extract has been obtained. On one occasion a constitutional reaction resulted from a dose of 015 mgm. Nitrogen, in which the symptoms of the mittal attack described above were duplicated.

Case II Female, aged 29 has had hay fever of moderate severity for 4 years. The patient was first even two weeks prior to the commencement of the ragweed season. The usual tests were made on the thigh, adjacent to the knee, and it was determined that the pitient belonged to the class A group ragweed pollinosis. A severe local rection occurred in the tested area which lasted for three days at which time it was noted that a definite circumscribed derinatitis was present suggestive of a weighning eczema. The patient stated that the eczematous area was similar to a rish which she had noticed occurred on her face and neck during previous hay fever seasons. It was also noted that a derinatitis developed on the arms in the areas in which the subcutaneous therapeutic injections were given. The patient had a severe attack of hay fever on August 16th. On August 20th a rash eczematous in character developed on the lower right side of the face and neck.

The rash on the arms was prevented by injecting the pollen extract more deciply (by using a 34 in, needle) and the face and neck were treated with local applications. The condition subsided about one week before the serson terminated. About a 40 per cent result was obtained chiefly because treatment was begun too late. In the three subsequent years no 13th developed and a 90 per cent plus result was obtained.

It is interesting to note that this patient normally perspired quite profusely about the head and neck Not improbably, the eczematous rash resulted from the solution of the pollen excitant in the perspiration. We must assume a greater tissue susceptibility in the areas effected. Blackley relates that he suffered from a dermatius of the scalp and face as a result of placing some rye (Secale cereale) in full bloom within his hat and wearing it on a hot summer's day in 1874.

Constitutional Symptoms There are no distinctive constitutional symptoms associated with hay fever Some individuals suffer from malaise, loss of weight, impaired appetite, constipation, insomnia, etc., which are correctly regarded as reflections of the catarrhal and asthmatic symptoms

Allied illergies In some patients, the hay fiver symptoms are aggravated by a concomitant sensitivity to other allergens. There are instruces in which a particular food, e.g. eggs, milk certain fruits, are found to disagree only during the hay fever season.

Variations in Intensity of Symptoms The symptoms are lessened or intensified according as the amount of pollen contained in the atmosphere decreases or increases. Plants

disseminate greater quantities of pollen on bright, warm, breezy or windy days, than during cloudy or rainy weather Patients are practically free from symptoms during periods of rain due to the fact that no pollen is shed at those times, and the atmosphere is cleared of pollen by the rain Symptoms are usually worse when the hay fever subject rides in a train or automobile, for thereby he is coming in contact with a greater amount of pollen per unit of time Patients are worse at night if the bed chamber windows are open to windward, for the same reason Frequently, exacerbations occur at night for the reason that, due to the cooling of the atmosphere after sundown, convection currents waft the pollen down from the upper strata

The Asthmatic Symptoms Hay Asthma, as the asthma caused by pollen is termed, should not be regarded as a complication nor as a particularly severe type of hay fever, but as a distinctive form of pollen sensitivity Clarity is attained by limiting the term hay fever to the catarrhal manifestations, i.e., to the oculo nasal pharyngeal symptoms, and hay asthmator pollen asthmator to the asthmatic symptoms. The term pollinosis includes both manifestations. The following is a typical case history

Female, aged 28 Mother and maternal aunt had hay fever paternal grandfather had asthma The first at tack occurred in 1919 (August 15th till the first week in October) It was then thought to be a severe cold ne diagnosis not being definitely made until the third season, when the symptoms were quite severe. The attack occurred each year about the same time and terminated not later than October 10th. In 1925, symp. toms began as usual about August 15th, and were con sidered somewhat milder than in previous years. On Sept 5th she retired about 10 o clock after a day of moderately severe symptoms At 2 30 that night, she was suddenly awakened by a sense of suffocation, marked difficulty in breathing and a distressful cough. The symptoms became so intense that she felt that death was impending. Relief was obtained after two hours, through a hypodermic injection of morphine During the remaining 35 days the patient had about 20 similar attacks of asthma After Oct. 10th the patient was quite well In 1926 her hay fever began as usual about dulte well in 1920 ner may rever organ as usuar arount status the astimatic symptom, however began about a week earlier than in the previous year, 1e, Aug 29th. That year the astimatic seizures were more severe and lasted for about 10 days after the termina tion of the hay fever symptoms. In 1927, and subsequent years treatment with ragweed pollen extract prevented the development of asthma and alleviated more than 90 per cent of the other symptoms

The important facts concerning pollen asthma

(1) Pollen asthma occurs in about 35 per cent of all hay fever subjects, (2) Its onset usually occurs after several seasons of the catarrhal symptoms, (3) Very often it de velops two or three weeks after the commencement of the season, (4) At first it usually ter-

<sup>&</sup>lt;sup>8</sup> The method and significance of the classification of hay fever patients according to the degree of sensitivity will be discussed in detail in a forthcoming paper treating of diagnosis.

minates before, or with, the hay fever season, but, (5) With succeeding years it tends to last longer each year. (6) There is no way of determining which hay fever subjects will ultimately develop pollen asthma. (7) The most effective method of treatment or prevention is that consisting of the subcutaneous injection of the correct pollen extracts in proper doses.

Seasonal Duration: In the major portion of the United States there are recognized three distinct hay fever seasons; (1) that due to the pollen of trees which extends from about the last week in March to the first week in June. The length of season of any particular case will depend on the genus or genera of trees in question. (For a fuller discussion the reader is referred to a previous paper.<sup>4</sup>) (2) That due to the pollen of grasses and plantain which extends from about May 30th to about July 17th. (This form has been dealt with in previous paper.<sup>5</sup>) And (3) that due to the pollen of weeds occurring from about August 15th to about the first week in October.

Duration: When once a seasonal attack has occurred it will recur each year at the same season for an indefinite period of years, if the patient be exposed to the particular pollen in question. One patient has suffered form the malady (the grass type) for 64 consecutive years with unabated severity—from the age of 4 to her 68th year. Individuals are frequently met with who have had hay fever for more than 25 years. It frequently happens that the symptoms are progressively lessened in severity in the later years. Occasionally one observes a bona fide case of hay fever, in which a spontaneous cure has occurred. Such occurrences, however, are rather infrequent. Instances have also been observed in which a spontaneous change of clinical sensitivity has occurred, e.g. a ragweed case has ceased to be clinically sensitive to ragweed pollen, but has developed a clinical sensitivity to grass pollen.

Variability of the Symptom Complex: There are three essential requisites for the development of hay fever—(1) a specific antibody, present in the blood serum (termed reagin) correlated with, (2) a specific pollen to which the patient is sensitive and (3) the tissue factor or so-called shock organ, which determines the particular clinical picture. In consequence of the variability of the third factor there results the variability of the hay fever syndrome.

There are patients in whom the eye symptoms predominate, and others in whom the nose is the chief source of trouble, and so on through the varied gamut of symptoms. The eyes may virtually be the only source of symptoms, the nose being entirely unaffected, and vice versa. Yet it is obvious that both organs are equally exposed to the pollen. There are, on the other hand, others in whom the malady expresses itself entirely or almost so, as pollen asthma.

From an analysis of cases observed during the past 10 years, it is ascertained that the most prominent symptoms (prior to treatment), showed the following distribution—nose, 45 per cent; eyes, 42 per cent; palate and pharynx, 10 per cent: ears (eustachian tube), 3 per cent. Probably not more than 2 per cent suffer from any skin manifestations of the malady. About 35 per cent of all hay fever subjects ultimately develop pollen asthma.

Termination: One of the most remarkable features of the hay fever syndrome is the almost dramatic suddenness with which it frequently terminates. A patient may suffer most intensely on Monday and awaken on Tuesday free from symptoms, to remain so. planation lies in the sudden disappearance of the offending pollen, or of the necessary concentration from the atmosphere. The transition from a condition of highly inflamed and irritated mucous membranes to that of subjective and objective symptomatic freedom is often a matter of a few hours. In other instances, the termination is gradual, due to the gradual disappearance of the offending pollen, or to a superimposed or associated bacterial rhinitis.

Complications and Sequellae: In the majority of cases of hay fever, there are neither complications nor sequellae, particularly as regards the catarrhal symptoms. It is a characteristic of the malady that a patient may suffer from ophthalmic and nasal pollinosis annually for many seasons, with no apparent pathology in evidence in the interims. is all the more remarkable when one considers the intensive character of the symptoms and signs. The explanation quite probably lies in the fact that the inflammation is caused by a chemical irritant and not by bacterial invasion. Chronic conjunctivitis and chronic rhinitis do occur as the result of a superimposed bacterial infection; such manifestations are to be regarded as sequellae. The catarrhal symptoms readily augment any tendency to the development of sinusitis.

A not infrequent sequellum to hay asthma (pollen asthma) is perennial asthma. In some such cases the period of asthmatic sequences

<sup>&</sup>lt;sup>4</sup>Thommen, A. A.: Hay Fever: The Spring Type. Studies in Hay Fever II. Medical Journal and Record, May 21, 1930; pp. 496-501.

<sup>\*</sup>Thommen, A. A.: Hay Fever: The Summer Type. Studies in Hay Fever III. New York State Jour. of Med., May 15, 1930; pp. 577-583.

is extended further each year, beyond the hay fever season, so that the patient ultimately becomes a chronic asthmatic, with seasonal exacerbations.

Finally, there is a form of the most severe asthma, which appears to be ushered in by a more or less mild pollinosis. The patient develops hay fever and pollen asthma which

speedily becomes perennial asthma of the most severe and recalcitrant type. The specific pollen sensitivity which is easily demonstrable by skin tests plays no further part in the syndrome, i.e. there are no pollen-season exacerbations. This form of asthma is fortunately rare: the writer has observed only five such cases.

### PHYSICIANS AND THE PHARMACOPOEIA

By W. A. BASTEDO, M.D., NEW YORK, N.Y.

Among the delegates to the Decennial U. S. Pharmacopæial Convention held at Washington, D. C., there was a poor representation of physicians. Many of the medical colleges and societies, each entitled to send three delegates, failed to send even one. This would suggest that the Pharmacopæia is of little interest to physicians; yet a survey suggests, not that physicians do not care, but rather that they take the Pharmacopæia and its standards for granted. They have no working interest in the botanical descriptions, the tests of identity and quality, the best menstruum for this tincture or that, and assume that these will be taken care of by the proper persons. They do not figure that the business of the Revision, Convention can be of direct importance to them. They seem unaware that attempts have repeatedly been made to turn the Pharmacopœia into a pharmacists' over-the-counter book, rather than a legal standard for prescription drugs and their preparations.

In 1900 this same state of mind produced a similar small medical delegation, and the Pharmacopœia became a book that could not be approved by physicians. This aroused them and as a consequence they sent their delegates in large numbers to the Convention of 1910. But it was only after bitter controversy that they succeeded in re-establishing the principle of a restricted and exclusive Pharmacopœia. In 1920 there was little but routine business transacted and no controversy, as the physicians were yielded to on every point.

But for the 1930 Convention medical complacency dominated and resulted in a decreased medical delegation, and as a consequence the physicians nearly lost their timehonored and obviously logical privilege of deciding what substances should be admitted to the Pharmacopocia; but as the results of the efforts of the medical delegates, together with some friendly pharmacists, two resolutions that prevented this loss were passed. By one it was resolved that the Revision Committee of fifty should be composed of seventeen medical members and thirty-three non-medical members, the medical members to constitute the "Committee on Scope."

In regard to the second, a resolution was first introduced and loudly applauded by the pharmaceutical delegates that decisions of the (medical) Committee on Scope should be referred back to the whole committee for final action, the non-medical members of the whole committee as aforesaid outnumbering the medical members by two to one. This at once aroused the medical members to action and finally a compromise resolution was accepted that while the decision of the Committee on Scope should be referred back to the whole Committee for sanction, it would require a two-thirds vote of the whole Committee to overrule any decision of the Committee on Scope. Thus the privilege of the physician to say what therapeutic agents should be recognized by the Pharmacopæia was nearly lost to them and is not complete.

It would seem that the pharmacists had determined to dominate the Convention of 1930 and to take steps to make the Pharmacopœia an enlarged and non-selective book. Their delegation largely outnumbered that of the physicians, and it was only by good fortune or the pharmacists' fear of offending physicians that the compromise resolution and not the original one, was passed. Therefore, if we wish the Pharmacopæia to continue a high-class exclusive book of standards it behooves the physicians to keep these events in mind and not to fail to send their delegates in large numbers to the Convention of 1940.

# THE PRACTICAL APPLICATION OF A MENTAL HYGIENE CLINIC (PROGRAM)\* By NOBLE R. CHAMBERS, M.D., SYRACUSE, N. Y.

NE of the most salient features of modern medical science is the emphasis upon preventive medicine and the emphasis upon the prevention of mental disease is peculiarly and particularly striking. The term mental hygiene needs no definition before this group. It is nothing absolutely new. Progressive psychiatry had been trying to do more than merely diagnose, classify and treat mental disease and by mental disease let us refer not only to the psychoses but also to the psychoneuroses and that great challenge; the psychopathic personalities. It had been making an effort to prevent mental disease. Now as the mental division of modern preventive medicine, the mental hygiene movement has become a part of the public health program and we find that not only psychiatrists but also psychologists, sociologists and lay people are vitally interested in attacking this problem—"how shall we prevent mental disease?"

The solution of the problem is theoretically simple—and is simply this—Establish in every community center of sufficient size a mental hygiene clinic. But an age-old conflict (and not a subconscious one) confronts us; that between theory and practice. The theory is plausible but many obstacles confront us in putting it into practice as we have learned in our efforts in Syracuse.

For the past few years the Mental Hygiene Committee of the Onondaga Health Assn. has been endeavoring to put over, if I may use the vernacular, a mental hygiene program in Syracuse, N. Y. and vicinity. We have just scratched the surface—we have made a start. But experience is a great teacher and as a member of the Committee without boring you with statistics I would like to relate briefly some of our experiences in the practical application of a mental hygiene clinic or program if you wish. And if I may be allowed to I shall include in some instances not only our experience in the line of mental hygiene but the entire field of neuropsychiatry as well. Much of this historical review up to a year ago comes from a survey of the mental hygiene movement at Syracuse made by one of my colleagues.

It seems needless to recall the history of the treatment of the insane—the demoniacal conception, the chains and the brutality afforded the patient. Philippe Pinel in the early part of the 19th century treated patients without mechanical restraint and just previous to this Wm. Tuke had founded probably the first asylum in New York. Connelly and Grieninger struck off the chains and attempted a sympathetic understanding of

the nature of mental processes. Then came the scientific psychiatrists such as Meynert, Wernicke, Kraeplin and Bleuler who considered the insane as sick individuals rather than as incomprehensible creatures. And lastly to Dorothea Dix of Maine goes the credit for being instrumental in organizing 32 asylums thruout the country.

So we find that just prior to the 20th century psychiatry was concerned with the hospitalization of patients and attention to their physical com-There were zealous endeavors toward clinical analysis and classification. There was as yet no effort directed toward the prevention and early care of mental disorder. It remained for Clifford Beers, Dr. August Hoch, Wm. James, Adolf Meyer and others to make the first great organized attempt to cope with the prevention and early care of mental disease when in 1909 the National Committee for Mental Hygiene was organized. One year later in 1919 the N.Y.S Committee on Mental Hygiene of the State Charities Aid Ass'n. was established which worked and still works in close contact and cooperation with the State Hospital Commission and the State Commission for Mental Defectives (both now merged into the State Mental Hygiene Commission). One of the main activities of these commissions or this commission was or is the conducting of mental, in reality mental hygiene clinics particularly in the smaller communities thruout the state. Some of which the writer had the good fortune to conduct. These clinics were handicapped by the lack of adequately trained psychiatric social workers and to a lesser extent by adequately trained psychologists. In many communities there was a splendid spirit of cooperation, but let me say here that while the adequately trained psychiatrist is perhaps the foundation of the clinic he is in dire straits, in most cases, without the above mentioned aids. A socal worker who is not properly trained and capable for this work not only does no good but all too frequently spoils the possibility of future contact for a capable worker and a mere psychometric examination stating M.A., B.A. and I.Q. is admittedly of little value. There must be an interpretation. Orton's work with reading disabilities has shown that many cases thought to be defective possess a normal intelligence. The psychologist is an important and valuable member of the clinic personnel.

The great difficulty with this plan was that many of the larger communities were left to shift for themselves and many did it creditably and many not so creditably. I shall not go into the history of experiences of other communities as there are many here who are more familiar with that situation than am I. Let us turn now

<sup>\*</sup> Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y., June 6, 1929.

to Syracuse, not with the idea of presenting an historical retrospect but with the hope that our experiences may be of value to some of those who are here today

In 1908, as a result of a law passed that year making illegal the detention of the instine in penal institutions a city Psychopathic Hospital was established-the first municipal psychopathic hospital in New York State The first director was Dr Hersey Locke, who was until his death in 1922 professor of psychiatry in the Syracuse University College of Medicine I will say more of this hospital later. In 1914 with keen awareness of the lack of interest in Neuropsychiatry Dr Locke instituted at the Syracuse Free Dispensary, as a part of the medical department, a neuro psychritric clinic with a definite trend toward n ental hygiene In 1920, after six years of in tensive work and still maintaining his warm interest in it he relinquished the work to the Asso crate Professor of Psychiatry at the College of Medicine This clinic has developed and is the basis of our present mental largiene clinic shall have more to say concerning this clinic later

In 1920, in line with the irresistible interest in preventive psychiatry or mental hygiene current thruout the country, the idea of a local mental hygiene committee later to be known as the Mental Hygiene Committee of the Onondaga Health Assn, the local administrative agency of the State Charities Aid Assn took form It was comprised of a selected lay and professional personnel from the health Dept, the public school system, the University and its Medical School and other organizations. Its purpose was chiefly to create and crystallize local interest and to aid in a concrete way in solving as far and as well as possible problems of mental disease. Well do I remember the organization meeting held during a meeting of this the N Y S Medical Society in Syracuse in May 1925 when the aims and ideals of such a committee were defined and stressed by Dr Lewellyn Barker and our own beloved Dr Thomas Salmon, whose recent death left such The committee's accomplishments a great void may be briefly summarized as follows -Addresses at luncheon and other meetings of the committee by Dr Stanley Davis of the SCAA on The State Program for Mental Hygiene, Dr Richard Hutchings of the USH "Problems of Adolescence, Dr C C Carstens of the Child Welfare League of America "The Study and Care of Problem Children," Dr Wm Healy "Tru-Other speakers at these meetings have been Dr George Pratt, Dr Lawson Lowrey, Dr Marion Kenworthy, Dr George Kirchwey and Dr Wm T Shanahan In addition to these ad dresses Dr Healy addressed a group of 800 school teachers and also discussed mental hygiene Lefore the Onondaga County Medical Society

the first public address was given by Dr. Frank wood Williams of the National Mental Hygiene Committee, defining the principles and practice of mental hygiene. Of course an educational ampugin was instituted. It consisted of news paper accounts talks to school teachers, mothers clubs social workers, nurses, radio talks and the distribution of some 2500 pamphlets. The Committee has in co-operation with the University. The Stracuse Health Demonstration and the State and National Mental Hygiene Committees given two series of lecture courses for parents teachers, nurses students and the public in general on the general topic of mental hygi ne of Childhood. The first series was given at weekly intervals. Topics and speakers were —

Your Mind and You—Dr George Pratt Heredity and Environment as a basis for Men

tal Health-Dr A Meyerson

Habit Training for Young Children—Dr Law son Lowry

Relationship between parents and children— Dr Esther Richards

Special Abilities and Disabilities—Dr. Augusta Bronner

The Delinquent Child and the Delinquent Community—Dr. Ir i S. Wile

Mental Problems in the schools—Dr Marion Kenworthy

Special problems of the High School Years— Di Arthui Ruggles

Capacity and even overflow audiences greeted the speakers and altho not intended a profit was made which was utilized to establish fellowsh ps to provide intensive training in mental hygiene for selected school teachers. Driven by the impetus afforded by these lectures the University established in extension class in mental hygiene

A second set is of lectures was given last year by Dr. George Pratt taking up the Mental Hygiene of Childhood intensively. They were also very well attended and added a helpful stimulus to the interest already aroused.

Another accomplishment of the Committee has been the work in the schools. An intensive study has been made in two schools and a third school is now being included. I will revert later to this work.

A third accomplishment and one in which the committee is particularly delighted is the promise of a State Psychiatric Hospital in Syricuse. It will be completed in about a year and will be like the Psychiatric Institute in New York for intensive study of cases. It will function in close co-operation with the University and the new Medical Center and will mark a distinct step forward in the treatment preventive as well as drig nostic, of mental disease in Syracuse and vicinity

The most recent accomplishment of the committee has been the re-organization of the S. P.

C. C. and the endeavor to procure adequate child placing facilities. Our work is useless without successful follow-up.

The field of operation for a mental hygiene clinic or program and may I include the whole content of Neuropsychiatry is much the same regardless of locality so while I shall consider only Syracuse our experiences might apply to anywhere. Just as Dr. White has said "Childhood is the Golden Period for Mental Hygiene" so our mental hygiene program is largely limited to that age. We have the pre-school and the school child to consider. We have also the problem of delinquency where we see both child and adult in the courts. We have the problems in the venereal disease clinics. We have also the organic diseases of the nervous system, the psychoneuroses and psychoses to contend with. To meet the above problems we have the city Psychopathic Hospital, several general hospitals, the clinic at the Syracuse Free Dispensary and the school clinics for pre-school and school children. The Juvenile Court clinic has been temporarily discontinued for reasons to be discussed later. Our personnel consists of five psychiatrists, all of whom are in private practice. We have three psychiatric social workers, two in the schools and one in the dispensary and one psychometric examiner in the employ of the Dept. of Education. Additional social service is afforded by the Associated Charities, the city and county probation Depts., women's organizations and luncheon clubs. There have been, of course, minor disagreements and contentions, one or two of which I shall mention later, but on the whole in view of the many variously interested individuals and organizations there has been a splendid spirit of co-operation. The misunderstanding of which most of you know between the Milbank Fund and the physicians of Syracuse reflected itself but little if at all on the field of neuropsychiatry, and this, in spite of the fact that the Mental Hygiene Committee is in reality a part of the Syracuse Health Demonstration sponsored by the Milbank Fund thru the S. C. A. A. I am glad to say that peace at least ostensibly again reigns. The clinical management is now under the professional rather than lay control as it should be while the business management is the reverse, as it perhaps should be.

In the concluding portion of this paper, I am going to presume to criticise our past work and equipment and to make suggestions for the future. These criticisms and suggestions, are not for the most part personal but are the views held also by my colleagues and the social agencies and workers possessing an adequate knowledge of the subject. We appreciate the fact that we have just begun, that the major part of our program is ahead. We doff our hats to the success of clinics held in New York, Cleveland, Philadelphia and other places and hope that some day the City of

Syracuse may also be able to boast a permanent and successful mental hygiene clinic.

Turning to criticisms; the city psychopathic hospital which started so gloriously as the first municipal psychopathic hospital is now little short of deplorable. It is merely a place of detention little more than a jail. No facilities for treatment are provided and only an ordinary examination is possible there. The position of the City Psychiatrist in charge of the City Psychopathic Hospital should be full time rather than part time which it is at the present time. The salary which is disgracefully small should be adequate. Althowe do not know the plans of the State Dept. for Mental Hygiene, the new state Psychiatric Hospital will undoubtedly remedy this entire situation.

The Neuropsychiatric clinic at the Syracuse Free Dispensary is perhaps the center of our present activity. It meets twice weekly from 2-4 P.M. and examines adults and children presenting any type of neuropsychiatric problem including neuro-syphilis. Here the city school psychiatrist does part of his work, the rest being done in the schools. There are two psychiatrists present on each day, a nurse and one psychiatric social worker. The Utica State Hospital conducts a parole clinic one of these days and affords an opportunity for psychiatric consultation with the local psychiatrists. The senior medical students attend the clinics in groups thruout the school year. This clinic is tremendously overloaded and lacks system. Good work with functional cases is practically impossible. The only remedy for this situation is the strict limitation of work, the making of appointments and the exclusion of students from functional cases until after a staff conference. Only recently have these been held. It is possible and probable that the new state hospital will relieve this situation particularly in regard to the psychoses and psychoneuroses.

The delinquency problem is another deplorable condition. Until very recently the conditions at the Juvenile Detention Home had been wretched but finally thru the efforts of the Judge and other interested parties we have succeeded in obtaining the old city hospital for this purpose. Here there is plenty of room and conditions are much better, but an adequate farm school and adequate child placing facilities would almost obviate the necessity for a juvenile detention home. Very little psychiatric work is being done with adult delinquents and at the venereal disease clinic.

The work in the schools is being done most nearly ideal but it is very, very far from what we desire. Limitation is practiced and there are two psychiatric social workers and one psychologist. No attempt is being made to cope with the delinquency problem. For several years the writer attempted to deal with the Juvenile Court Problem on a voluntary basis. Some 6 months ago in

accord with the opinion of the Onon. Health Assn. the work was discontinued The Judge and the probation depts. both city and county had cooperated to the extent of their ability but they were without adequate training and this clinic was without a psychiatric social worker and a psychometric examiner which are such vital necessities for the successful operation of such a clinic. Both the school work and that in the Juvenile Court are very greatly handicapped by the lack of adequate child placing agencies so that at least many times the work of a disgracefully underpaid City School Psychiatrist for the Board of Education and his staff was to no avail for recommendations could not be carried out. The first great step in this regard has been made recently when the S. P. C. C. was re-organized as mentioned previously. We are anticipating the resumption of the Juvenile Court work in the near future with an adequate staff, but at present no new examinations are being made. cannot be ideal at the start as some of the committee would like and I would favor the resumption of this work at the earliest possible date.

There is at present no organized mental hygiene clinic for University students but the Associate Professor of Psychiatry sees those who come to him for aid. There is no use being made of the Depts. of Psychology and Sociology at the University except that a few students are doing field work at the Juvenile Detention Home not with the sanction of the Mental Hygiene Committee, but under a director, obtained by the City and the University Dept. of Sociology without con-

sulting the committee.

It is very difficult to examine functional cases at any of the General Hospitals, alone in a sound proof room as should be provided. More training both actual and practical in mental hygiene should be provided in the nurses traning schools of these general hospitals and affiliation made with the nearby state institutions. Visits to the Syracuse State School for Mental Defectives have been of great value to one of my classes.

It must be apparent to my audience that there is a tremendous problem ahead of us in Syracuse. This has possibly been partially solved in a survey of child welfare with recommendations made by Dr. Carstens. Unfortunately our educational campaign was premature and our practical work has lagged. Again I say we must make a start as soon as we can operate efficiently.

Motivated by the advice of Dr. Lawson Lowry, to make use of all existing agencies at least temporarily and to free the work from

municipal or county control as soon as possible, the writer presented a year or more ago to the medical director of the State Mental Hygiene Commission a temporary draft of a plan of solution of our problem for what was then to be called the Onodaga County Mental Hygiene Clinic but later changed to the Onondaga County Neuropsychiatric Clinic to include the whole Neuropsychiatric field as outlined above. At the suggestion of the above mentioned medical director and fellow members of the Mental Hygiene Committee of the Onondaga Health Assn. a child guidance clinic was incorporated into the plan An Institute of Research in Education and Character sponsored by the Associate Professor of Educational Psychology at the University has recently been organized and will fit admirably into the plan.

I believe that in this plan lies the solution of the practical application of a mental hygiene clinic as applied to Syracuse and vicinity It provides that the clinic be under the joint directorship of the new state hospital and the Supt. of the State School. It is to be staffed by the local neuropsychiatrists who show an interest in it and are adequately trained. They will be adequately paid for their work which will be part time. It is to work in close co-operation with the Neuropsychiatric Division of the Medical Dept. of the University. It is to make use of all existing social agencies and the University Dept's, of Psychology and Sociology under proper guidance. Its field is to be the pre-school and school work, the delinquency problem, the organic nervous diseases, the psychoneuroses and the psychoses. In association with this clinic there will also be a child guidance clinic for very painstaking work as well as the Institute above mentioned. Funds will be difficult to obtain and progress slow but it can be done.

In conclusion, if this relation of our experiences in Syracuse and vicinity in the practical application of mental hygiene clinic has been or may be of any value in guiding other communities in establishing a mental hygiene clinic, my time in preparing and your patience in listening to this paper will not have been in vain. If any generalities can be made they are; -things cannot be perfect at the start but be sure to have adequately trained and paid psychiatrists, psychiatric social workers and psychologists, be sure the child placing facilities are adequate, use all interested persons and organizations of course under proper guidance, then go ahead, their is a great field awaiting.

#### TUBERCULOSIS WITH LARYNGEAL TREATMENT OF THE ARTIFICIAL SUNLIGHT\*

By JOSEPH W. MILLER, M.D., F.A.C.S., NEW YORK, N.Y.

HROUGH the untiring energy of Dr. Wessely, the university throat clinic, Hajek of Vienna has brought forth in the last few years a very ingenious method of treating tuberculosis of the upper air passages by means of concentrated artificial sunlight.

The development of concentrated artificial sunlight. Heliotherapy for tuberculosis in general and laryngeal tuberculosis in particular is not new. The healing power of the sun was surely known to ancient civilization. The Egyptians, Persians, Greeks and Romans employed sunlight for therapeutic purposes and probably have quoted the elder Pliny's "Sol est remediorum

During the long sleep of the dark ages, heliotherapy was blotted out and modern aspects of the subject are as recent as thirty years ago; when Poncet began to use sunlight in the treatment of tuberculosis. His work made little or no impression and was left unnoticed. It was Finsen of Copenhagen who in the late 90's made the world watch him when he employed condensed sun rays in the treatment of lupus. From a scientific standpoint he was the founder of modern heliotherapy and was also the first to find in the carbon arclight an excellent substitute for sunlight which was especially effective in lupus.

However, it was Sorgo who first treated tuberculous lesions of the larynx with reflected sunlight, and was able to demonstrate a number of successfully treated cases twenty years ago.

Strandberg, working in the Finsen institute, reported relatively favorable results, using an ordinary carbon arclight in the treatment of laryngeal tuberculosis. His encouraging results impressed Prof. Hajek and he delegated his assistant, Emil Wessely to investigate the value of the carbon arclight with regards to its use in the treatment of tuberculosis of the upper air passages.

It was Wessely's intention not only to test the favorable results obtained by Strandberg but to investigate the physiology and biology of sunlight and its substitutes with a view of producing an artificial source of light resembling sunlight. Since it is known empirically and theoretically that the maximum amount of light energy causing erythema and pigmentation is due to the waves having a wave length of  $300\mu\mu$  and that these are located at the outer or blue end of the spectrum, i.e., the ultraviolet end, Wessely began to experiment with these rays to the exclusion of all others.

The plan was to imitate the blue end of the sun

spectrum as closely as possible, by the employment of a tremendous light energy and an apparatus which would allow the light energy to strike unaltered at a desired spot.

The carbon arclight yields rays closely resembling sunlight but the ordinary arclight in itself is not the best imitation of sunlight. With the addition of a certain substance-metallic saltto the carbon bars, the blue end of the spectrum becomes complete. Such impregnated earbons are now manufactured by the optical concern of C. P. Goerz Co. of Vienna. These impregnated carbons yield rays having a wave length of 290μμ, embracing the entire ultraviolet of high altitude sun at zenith. The spectral analysis of these carbons were made by Prof. Hascheck of Vienna.

In order to destroy tuberculous tissue, powerful and concentrated light is necessary; light of the inner ultraviolet having a wave length of  $300\mu\mu$  or thereabout. All this has been scientifically accomplished in the Wessely Radiation Machine (modified carbon arclight). By a specially designed Goerz system the superficial brightness is doubled, which also shortens the time of exposure to irradiation.

The following requirements are necessary for this artificial light to be of value: It must be a chemically active, cool light of a suitable photochemical intensity. It must be concentrated so as to reduce the time of exposure to a minimum and at the same time create an optimal therapeutic These requirements are all fulfilled by the Wessely machine which is an arclight burning with specially constructed and impregnated carbons according to the Goerz system, by which the greatest concentration of rays is thrown to one side and made to converge into a cone through the medium of a quartz optic. In other words, this machine is a carbon arclight water-cooled quartz lamp.

With this lamp only one patient at a time can be treated, either directly by means of the Seiffert direct universal laryngoscope or indirectly by means of an all-metal laryngeal mirror. Those in good general condition or otherwise favorable subjects without involvement of the epiglottis are irradiated directly. Patients so treated have the benefit of the rays striking the lesion, thus shortening the period of treatment considerably. Frail individuals or those with advanced pulmonary lesions or those intolerant and too sensitive and with lesions of the epiglottis are treated indirectly in the sitting posture by means of an all-metal laryngeal mirror held suspended by a special contrivance attached to the teeth.

Steel mirrors are utilized because they reflect

<sup>\*</sup> Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y. on June 5, 1929.

about 44% of the valueable therapeutic rays into the larynx; while the ordinary glass mirrors absorb these rays reflecting only about 9%. This method is not as effective as the direct method but it is more comfortable. The patient sits in front of a large mirror which is centrally perforated like a head mirror and can observe his own larynx. In this manner he is able to regulate the laryngeal mirror himself whenever the rays do not strike at a desired area.

The results obtained by Wessely in Vienna prompted me to import this machine to the United States in 1925. One year later the trustees of the Beth Israel, Hospital, on the advice of Dr., S. J. Kopetzky have installed this machine in the out-patient department and organized a special clinic for the treatment of laryngeal tuberculosis in conjunction with the bronchoscopic clinic.

Before treatment is begun, the patient's condition is determined carefully A thorough chest examination both physical and roentgenological is made; the sputum searched for tubercle bacilli and the blood examined to determine the relative rapidity of the sinking of the erythrocytes (Fahreus). These examinations are repeated on several occasions and compared Thus we soon have an index to determine more or less accurately the status of the patient from time to time.

Of course, the best results are achieved in those patients having a good resistance and a relatively good power of regeneration. Such patients are those with mild pulmonary lesions which either become arrested or else show slight progression. These forms are usually afebrile or subfebrile and yield either normal or slightly elevated sedimentation tests (Fahreus). As far as circumscribed processes are concerned, in a certain number of cases the use of the cautery, or, in tuberculomas, the actual surgical removal may bring about healing much sooner. But here one also must remember that in certain localities these measures are dangerous; such as the anterior commissure where a matting of the cords may take place and in the region of the processus vocalis with resulting perichondritis and ankylosis. In such localities the treatment with artificial sunlight is safe and gives best results, though it may take from three to six months to accomplish it.

While in a great majority of cases the local light treatment has no effect at all on the primary pulmonary condition, in a great number of cases we have observed that with the healing of the local lesions, there is a general well-being of the patients; the fever slowly subsides, and his pulmonary condition improves. On the other hand, we have seen cases where the pulmonary condition

tion remained the same or became worse and yet healing and cicatrization was brought about in the tuberculous lesions of the larynx. Case No. 5 will illustrate this point clearly. In such cases, it takes months to bring about healing but it is accomplished nevertheless.

However, in a great number of febrile cases, local healing is never accomplished. While the lesions remain stationary, the pain disappears. About the analgesic action of sunlight much has been written and its blessing has long been known. That there are cases, because of low resistance and rapid pulmonary involvement, in which the light has no effect at all, I mentioned above in this article and also in a previous article on the subject.

Of the 74 patients treated both in private practice and at the bronchoscopic clinic, we found that laryngeal tuberculosis is somewhat more common in the male. In our series of cases the disease occurred most frequently in Italians especially young Italian girls between 17 and 22 years of age. The youngest patient was 16 years and the oldest 73. The most frequent site of the lesion was the interarytenoid space and arytenoid area either in the form of ulcers, tuberculomas, or pear shaped infiltrations. The next common locality was the epiglottis also either in the form of ulceration or infiltration. The vestibule of the larvnx and the cords were next frequently involved. And last but not least, we found that malignant type of tuberculosis which is described as a diffuse infiltration of the entire circumference of the larynx. In this form the swelling and infiltration are not limited to the mucous membrane only but take in the deeper structures giving rise to a diffuse tuberculous perichondritis which, if the patient lives long enough soon collapses and is destroyed by a process of caseation necrosis. The resulting ulcerations are extensive and respond to light therapy only when the patient's resistance is good and his pulmonary condition stationary. But in most cases with a diffuse tuberculous perichondritis, we have a fulminating progressive pulmonary involvement which shatters the victim's resistance and brings about his end in short order.

During the course of treatment, the patients general condition is looked over from time to time and the febrile cases and those showing progressive pulmonary involvement or loss of weight or strength are put to bed for weeks at a time as soon as the agonizing dysphagia has disappeared. Complete rest in bed, fresh air and good food is the best therapeutic trio in all forms of progressive tuberculosis.

As to the special value of a high and dry mountainous climate in pulmonary tubercu-

losis we agree with Fishberg that in many cases it only tends to break up the home in as much as a good many sufferers would be better off where they could get plenty of rest and good food and not be obliged to shift for themselves in the country. Everything depends upon the course of the disease. Febrile cases with rapid progressive lesions usually run to a fatal termination no matter where and how soon they are dispatched to the country. On the other hand, the slowly progressive chronic types with or without occasional elevations of temperature, will linger on for years or their processes may become arrested altogether even in large cities under favorable home-like surroundings. But in laryngeal tuberculosis, particularly the ulcerative types, the country is of no use at all. What benefit is the fresh air to the sufferer when he or she is unable to swallow? Such cases are much better off in the city or at a sanatorium devoted to the treatment of laryngeal tuberculosis.

# Report of Cases

Case No. 1. Chas. St. J., age 37, referred from tuberculosis clinic of the Dept. of Health on Dec. 14, 1925. Complaint; hoarseness for past five months and slight pain on swallowing for past six weeks. Has had pulmonary T. B. for several years; with cough and expectoration.

Examination:—Infiltration of both ventricular bands partly covering the vocal cords. The latter do not approximate centrally. The interarytenoid space was filled with tuberculous granulation tissue. The sputum was bacillary and Fahreus test shows a sinking speed of 15% in 45 minutes.

First treatment on the 22nd of December 1925 and on every other day thereafter until 17 treatments. All exposures were direct via the Seiffert's direct universal laryngoscope with chest support and lasting for from 8 to 10 minutes. Following the second exposure the pain on swallowing disappeared entirely and after 15 treatments the voice became quite normal. The ventricular bands assumed a normal aspect and the masses in the interarytenoid space gradually faded away. He was discharged on Feb. 18th, 1926 and left to find work out of town.

Case No. 2. Miss L. R., 42 years of age was referred to us from Arizona where she was confined to a Sanatorium for the treatment of her pulmonary tuberculosis. Her complaint at the first consultation was that of increasing hoarseness, cough and expectoration. Her pulmonary condition dates back for many years, she being very much familiar with the nomenclature of tuberculosis and offers information

as to how many cavities she has and where they are located. Hoarseness began gradually in September 1925.

Laryngoscopy on the 5th of April, 1926, revealed swollen and congested cords, slight infiltration of the arytenoid region and granular masses in the interarytenoid space. The pulse was 96 and evening temperature 99°. Respiration was asthmatic, she was somewhat cyanosed, her sputum was bulky tenacious and bacillary. Fahreus 24% in 45 minutes.

First irradiation on 5th of April, 1926, indirect exposures ten minutes every session on alternating days. Total exposures eighteen making a combined total of three hours of actual irradiation. During the course of treatment her voice gradually cleared and soon assumed a normal tone. The last we heard from her she had a thoracoplasty performed recently at the Mount Sinai Hospital to put at rest her diseased lung. Her larynx, however is healed to this very day.

Case No. 3. Dorothy R., 18 years of age, came on 18th of February 1926, complaining of hoarseness for past six months, cough and expectoration for past five weeks. Ten days prior to her first visit she began to experience slight pain on swallowing which became progressively worse as time went on and at the time of the examination was unbearable. She was only a few months in this country having emigrated from Russia where she had to go through a severe ordeal in her early childhood during the war and was forced to subsist for months at a time on turnips and various other herbs.

Examination:—Revealed extensive infiltration of the entire larynx interior and circumference. The appearance was that of a waxy rigid mass involving the deeper layers. The entire picture was one of an acute fulminating tuberculous perichondritis. Roentgen examination of the chest as reported by Dr. Jos. Diamond "reveals an extensive peribronchial infiltration extending to the parenchyma of both lungs. These findings are indicative of an acute fulminating form of pulmonary tuberculosis."

The entire course consisted of 34 exposures of from eight to ten minutes each between the dates of 19th of February 1926 and the 17th of April 1926. After the fourth exposure the pain lessened and after the tenth disappeared entirely. She could swallow food and drink with no effort whatsoever; but the appearance of her larynx objectively remained the same. In view of the fact that her subjective laryngeal sypmtoms subsided without any appreciable change in its pathologic structure and in view of the fact that the sinking speed of the erythocytes became faster as

time went on, we decided to suspend treatment and give her complete rest. For the next five months I was in communication with her parents who assured me that she was able to swallow food and drink painlessly. But the end came while sitting comfortably and looking through the window having no complaints to make whatsoever.

Case No. 4. M. J., 22 years of age, referred from tuberculosis clinic of Health Dept. on 8th of June 1927, with a history of having suffered from pulmonary tuberculosis for four years. The past few weeks he began to lose weight rapidly, had pain on swallowing and

was slightly hoarse.

Examination of larynx revealed a deep ulcer in the middle of the epiglottis extending deeply downward and inward to about its center. The rest of the epiglottis was infiltrated and there was some infiltration at both arytenoid regions. His weight at this time was 106 lbs. Fahreus 21° temperature 100 and sputum bacillary.

Dr. Stivelman reported on chest examination as follows:—Infiltration and multiple cavitation entire left lung, infiltration right upper lung, thickened pleura left lower, heart and trachea pulled to the left. X-ray cor-

roborates the above findings

Irradiation was begun on 9-6-27, patient reports on 11-6-27 that he is feeling better. He was irradiated three times weekly for ten minutes at each exposure. On 18-6-27 patient reports sharp pain in the left side of throat. On 28-6-27 patient is free from pain. On 18-27, ulcer practically healed and on 15-10-27 ulcer fully healed. The defect in the epiglottis was covered by a pale-looking epithelium Fahreus was 35% and weight still 106 lbs. Patient was advised to go to a sanatorium for his chest condition and was sent to Denver. From there patient writes "am feeling fine and having no trouble with my throat."

Case No. 5. Miss M. E., age 20, referred from the tuberculosis clinic of the Dept. of Ilcalth on 22nd of November 1927. Her history in brief was that until a year ago she was perfectly well, when she began to cough. She visited the Health Dept. and was told that she was suffering from pulmonary tuberculosis. No loss of weight, no night-sweats and

no hemoptysis

Examination: — Laryngoscopy showed a pear-shaped swelling of upper border of epiglottis tapering from right to left, infiltrated left arytenoid and tumefaction of the interarytenoid space. Fahreus 5% and sputum positive.

Chest examination as reported by 'Dr. Stivelman: — Infiltration and cavitation of right upper lobe, infiltration scattered radially from hilus of left lung. She was irradiated

from 26th of November 1927, to 22nd of June 1928, getting ten minute exposures three times a week. On the latter date the epiglottis was entirely healed and the swelling of the arytenoid almost completely subsided. Patient was sent for the summer to the country and returned to the clinic the last week in October with the larynx entirely healed. Her sputum, 'however, still showed occasional tubercle bacilli.

Case No. 6. Leonard C., 38 years of age, referred to us from the tuberculosis clinic of the Dept. of Health through Dr. Silberman

on 4th of January 1928.

History and complaint:—Cough and expectoration and gradual loss of weight for the past year. Pain in the throat especially on swallowing and slight hoarseness for the past eight months. Family history is negative and there is no specific history.

Physical examination by Dr. Stivelman "infiltration and cavitation of left upper pulmonary field and infiltration of right apex." X-ray corroborated the above findings. Fahreus 10% and sputum positive.

Laryngoscopy:—Laryngeal surface of epiglottis thickened and ulcerated in its middle so much so that it had the appearance as if a piece was bitten out.

Treatment began the 4th of January 1928 and terminated 8th of June 1928, at the rate of three exposures a week ten minutes each all in the indirect method. After the fourth irradiation, no pain on swallowing. The necrotic membrane covering the ulcer has now disappeared. After three months' treatment many islands of granulation tissue were seen budding from the floor of the ulcer which soon became epithelialized and healed over. He gained about 20 lbs. in weight and felt better generally. In this condition he left to find work during the summer time in the country.

Of the 74 cases treated, only two did not respond to radiation. One was a patient 73 years of age, and the other a young girl of 20. In both cases there was no subjective or objective improvement. Although the old man did admit for a time that he was feeling better, we are willing to discount that because of his anxiety to please and cooperate with us; and because it was only temporary. Both these patients were very frail, too far gone and had no regenerative powers. Of the other 72 patients, 59 showing complete healing of laryngeal lesions with no subjective symptoms referable to the larynx. The other 13 cases, while improving from their subjective laryngeal symptoms, demonstrated either partial or no healing of the tuberculous larynx. Of course, it should be emphasized

that even a greater number could have been successfully healed, were it possible to irradiate these 13 patients in a sanatorium where this mode of treatment really belongs.

Discussion by Dr. Roy S. Moore, Syracuse, N. Y.

Three years ago, I discussed the treatment of laryngeal tuberculosis before this section of the State Society, and at that time reported the results of the use of the Wessley lamp on forty odd cases. The cases were largely those having localized lesions of the larynx, found more frequently in Europe than in America. I wrote the superintendents of many of our larger sanatoriums for the treatment of tuberculosis to ascertain the extent of the use of light therapy. This spring I have again beenin touch with many of the same men. I find the work is being carried on today much the same as it was four year ago. All of the men feel that exposure of the whole body is of benefit in any type of tuberculosis. The use of the sun's rays indirectly into the larynx is practised considerably in the west where more

sunshine is available. Here in the East, the ultraviolet ray has been used rather half-heartedly in some institutions and by some men with indifferent results.

Nowhere else have I seen reported any such results as Dr. Miller brings to us. Through his courtesy, Dr. Harry Brayton and I had the privilege of meeting and examining many of Dr. Miller's patients. I examined and talked to his patients with healed ulcerations of the epiglottis, and old cases of perichondritis who told me that they swallowed water only with excruciating pain at the beginning of the treatment. The relief of pain in any type of case which can stand exposure, seems to me to open up a great field of usefulness. For many lung patients, the development of one or two lesions in the larynx, or on the epiglottis, means painful swallowing with consequent loss of weight from insufficient food, and the beginning of the end. When they can eat with comfort, they begin to regain their lost weight, and have a fighting chance.

# INTERESTING THE SMALL COMMUNITY By FREDERICK W. SEARS, M.D., SYRACUSE, N. Y.

SYCHOLOGY plays an important role in all public health work. This is especially noticeable in the smaller communities. The personality of the worker means much in all activities where the success of that activity depends on the voluntary cooperation of the public. Confidence in the physician and nurse is a great factor in relieving anxiety and securing cooperation. The health worker who can utilize all of these factors is the one who will meet with the greatest measure of success.

The gradual disappearance of the old time family physician has had a tendency to break up somewhat the close relations which have formerly existed between the patient and doctor. Yet in spite of the propaganda of the chiropractor and other cults and their ever present effort to discourage the efforts of the health worker the regular physicians still hold the confidence of the people when matters of vital interest to their families are concerned. Therefore our efforts in all communities should be, first, to secure not only the cooperation of the physician or physicians in the community but should secure his most enthusiastic assistance. Indifference on the part of the local physician is almost as bad as open opposition.

In one of the small villages of Onondaga County one elderly physician made a house-to-house canvass and secured the consent for immunization of eighty-five pre-school children.

'Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y., June 6, 1929.

and he stated to me he had secured the consent of all but six families in the village. This is an example of what may be accomplished by a physician who is thoroughly interested in the welfare of his community.

It is of great advantage where possible to have the physician bring his child for the first clinic treatment, especially if that child is of pre-school age. Patients are very skeptical regarding our advice if we do not practice what we preach, and the question which we are frequently asked is, "Would you give it to your child?"

In the cities the problem is largely an individual one because there is not that close social relationship in the neighborhood that there is in the more rural communities. In rural communities the people are more prone to follow leadership as there are usually a few persons in the rural communities who set the example in all public activities, and next to securing the cooperation of the physicians it is of the greatest importance to secure the endorsement and cooperative work of these leaders. Through the more rural sections the Farm Bureau, the Granges and other civic organizations play a very great role in molding public opinion. Addresses by competent speakers before these organizations will do much toward securing results. Another method which we have found very successful is talks to the school children themselves, urging the older ones to bring the smaller ones to the clinic and we frequently are able to make a very

good pre-school survey by asking the school children to collect the names of the younger children in their families and others in the neighborhood for us. This method has worked well even in the cities as we find that the parents will more readily listen to their own children than to strangers whose motives they have not been convinced are purely altruistic. For this reason we find that the house-to-house canvass in the villages has been very successful providing that the canvass was made by those who are well known in the community, but practically a failure in the cities. City people are less neighborly and it becomes more of an individual problem.

In 1926 we made strenuous efforts in the City of Syracuse to secure a high percentage of consents by means of house-to-house canvass by competent nurses. We were greatly disap-

pointed in the results.

The homes in the cities are exploited by all sorts of vendors rendering it difficult for a nurse to even get into the home to explain her mission and a large percentage of the people were either actually not at home or not at home to the nurses. If the nurses finally did get the mother sufficiently interested to sign the consent slip for her children it frequently happened that when the husband came home at night he refused his consent, therefore a large portion of time expended by these nurses was wasted.

In rural communities, however, the mother usually holds a supreme place in the rearing of her children. Her word is law so far as the children's interests are concerned and when she

gives her consent it is final,

Stress has been laid on the importance of immunizing the children of the larger centers of population as it has been shown that diphtheria tends to radiate from these centers. This is undoubtedly true as a public health measure but from the standpoint of protecting the individual it is also important to carry on the work in the smaller communities as 90 to 95% of the children in these communities are susceptible to diphtheria whereas in the larger centers only from 60 to 65% are susceptible to the disease.

Another factor which we have found of great importance is perhaps a psychological one by which we try to overcome the fear which parents have of immunizing the younger children in the family. Our plan in this has been to secure all we could for the first immunization dose and not exclude the children who are over ten years of age. A few days after the first dose is given we try and get a meeting of the parents whose children have been given the first dose as well as those who have not. We have this meeting addressed by someone competent to speak to them, answer all questions and point out to them the simplicity

and harmlessness of the treatment as shown upon the older children, urging them again to bring the smaller children to the next clinic. This, in our experience has led to great success, as many of these mothers are then not only willing to complete the work on the older children but will bring the younger ones when we have proved to them the harmlessness of the injections.

In one small village where we used this method we started with 163 first doses and we finished the three treatments with 357. Rural people are very cooperative once they have been shown that the treatment is not dangerous to their little ones. Here the personality of the worker plays a tremendous role in securing the immunization of these children.

I have been frequently asked if it is not difficult to get the children to come back for the second dose. My answer has been in the negative as practically in every instance we get a larger number of children in the second clinic than in the first, and it is only in a very few of the children that we were not able to

carry out the three treatments.

Cheerfulness and gentleness in handling the children and producing as little trauma as possible in giving the injections is a great factor in gaining their confidence. Those who have had a large experience with young children will readily endorse the fact that once they can gain the complete confidence of a child he is ready to submit to any kind of reasonable treatment.

Greater care is necessary in handling the children of these smaller communities so that no accident or unpleasant experience results as it is in these communities that news usually travels rapidly. I believe it is wise to endeavor to establish a simple technique which can be carried out rapidly and thoroughly with the least possible confusion. The room in which these clinics are held should be maintained as quiet as possible.

To summarize:

First: Secure the active cooperation of the physicians as it is their advice that will count with the parents in making the final decision.

Second: Secure the assistance of the women leaders in the community and where possible have a thorough canvass of the homes made.

Third: Give three-minute talks to the children of each school grade, urging them not only to get the consent of their parents for their own immunization, but also for the preschool children in the neighborhood.

Fourth: Make the village clinic the center for all of the school districts in the townships. The elimination of diphtheria in the smaller communities is a much simpler problem than

it is in the cities.

# OSTEOGENESIS IMPERFECTA TARDA (FRAGILITIS OSSIUM) REPORT OF FOUR CASES IN ONE FAMILY

By MORRIS GLEICH, M.D., NEW YORK, N.Y. From the Pediatric Service, Harlem Hospital, New York City

STEOGENESIS imperfecta appears to be a fetal or embryonal disturbance<sup>17</sup> due to faulty mesoblastic tissue.<sup>14</sup> This tissue, in turn, owes its poor quality to defects in the hereditary units (the chromosomes) of the parents' germ-cells.

Since we find only bone tissue affected in this disease, it seems as if the embryo or fetus begins its intrauterine life with an impaired osseous-forming mechanism. This hypofunction may be due to some endocrine disorder.

The fact that bone alone is involved speaks against some constitutional disease as the only cause. It is hardly likely that tuberculosis, lues, or alcoholism would exert such selective action, picking one system, and sparing the others, unless the individual or family had an hereditary predisposition or constitutional weakness affecting a particular system <sup>20</sup>

We are more inclined to look for an explanation in the Mendelian rule of Dominance.<sup>18</sup> Here the crossing of sub-species results in certain characteristics in the hybrid offspring; in our case, a deficiency in the mechanism for bone formation

R. H., a colored boy of nine years, was born in the U. S. A. His delivery was normal and at full term. He was nursed for ten months He had six teeth at a year. At 1½ years he attempted to walk. Soon it was noted that his legs began to curve anteriorly. At three years of age he suffered his first fracture, that of the left tibia. Operation was performed to straighten his legs. When he began to work or attempted to stand, the anterior deformity returned. He was compelled to use crutches.

A father, mother and six children comprised the family. The father broke his right femur five times over a period of 45 years. The first fracture occurred 25 years ago. Since then the slightest misstep caused fracture of the same femur. X-ray of his right femur showed marked deformity and osteoporosis. The right tibia and fibula also showed bending and marked decalcification (see Figure I).

John, another son, now fifteen years old, with a normal developmental history, walked at 3½ years. He broke his right tibia for the first time when he was three years old. Since then his legs have been broken 10-12 times. These fractures occurred either after direct trauma or an awkward step. Twice he slipped from his crutches and once he fell over a rug. Each time he sustained a fracture. X-ray of his tibiae and fibulae showed fractures, osteoporosis and antenor bowing similar to that of our

patient (Figure II). In addition, the left tibia and left fibula were markedly deformed.

Herbert, eleven years old, fell out of a high chair and fractured his left hip. X-ray of his femora, tibiae and fibulae showed no fractures. However, he had a bi-lateral coxavara and a lateral curvature of the right femur.

The other brother (four years old), two sisters (2 years and 17 years respectively) and the mother, did not give a history of fractures or deformed limbs. None of the grandparents

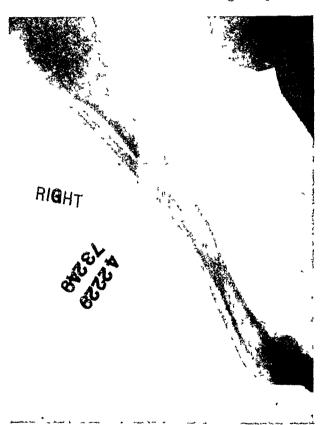

Fig I TATHER H.

Tibia and fibula show rarefaction and bowing Proximal end of tibia shows scent bony network while distal end is markedly osteoporotic Cortices thinned.

on the mother's or father's side had ever suffered fractures.

On the 9th of February, 1929, our patient (R. H.) fell out of bed and broke his right femur. He was pale, with flabby though painless muscles. His hair was soft and his skin smooth. His humeri and femora were somewhat curved laterally. A distinct, hard, callus was felt over the right femur. The lower third of both legs showed considerable anterior bowing His mentality was normal. The adipose

tissue and genitalia were normal. His teeth were in good condition. His eye-grounds were normal. There were no blue sclerotics. His chest and abdominal viscéra were negative.

X-ray showed a fracture at the middle of the right femur. The upper fragment was curved. Both legs showed bowing anteriorly. (Figure III). There were old fractures through the lower third of both tibiae. The skull showed no evidence of rarefaction. Any old evidences of a calvaria membranacea were not seen. A good deal of lime salts absorption was seen in all bones. The arms and forcarms showed no signs of a lesion. The normal rib contour was disturbed. It showed distinct depressions anteriorly near the costochondral junctions. Sella tursica X-ray showed the posterior clinoid processes to be larger than normal

Blood-serum, calcium and phosphorus taken semi-monthly, for four months were within

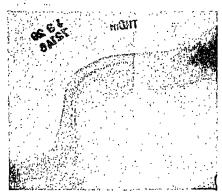

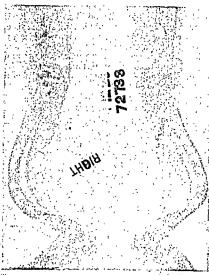

Fig. II-John H. 15 yrs. old. Rarefaction of tibia, fibula and tarsals extreme; Deformity marked; Fracture of tibia.

normal limits. They were: for Calcium—11.6, 10.7-10.6-10.4-10.5-11.6 Mg.; for phosphorus 4.3-4.4, 4.3, 4.6 Mg. per 100 c.c. Blood cholesterol was .240. Blood Kahn and Mosenthal tests were negative, Basal metabolic rate was normal. Blood urea 13.9 Mg. and creatinine 2.1 Mg. There was no sickling of red blood cells and several blood counts and urine examinations were normal. The calcium and phosphorus results were expected since we were dealing with an inactive case.

The strong hereditary tendency, the periosteal aplasia without endochondral (epiphyseal) involvement and the numerous fractures upon slightest causes, point to osteogenesis imperfecta. Osteomalacia is acquired, primarily affects adults (especially pregnant women), involves the spine and pelvic bones, as a rule,

and represents decalcification of normal bone, followed by osteoid tissue. Besides, the diaphyses rather than epiphyses are affected. One can hardly speak of these cases as late rickets. In rickets we see epiphyseal involvement. Fractures are not so evident or numerous and the response to irradiated ergosterol, cod liver oil, sunlight, even in late rickets, is prompt.

We were evidently dealing with quiescent cases of osteogenesis imperfecta. For this reason we were not surprised when adrenalin (by

- ked. Fracture

hypo), cod liver oil, Alpine light, acterol, pituitary substance (ant. and post lobes), calcium lactate, parathyroid extract and bone marrow, each given alone for periods of two to three weeks, did not produce any perceptible clinical or chemical results. However, our patient is now able to stand unassisted. We feel that time is an important adjuvant and that following osteotomy and the use of a brace or crutches he will have fairly serviceable limbs.

Since the pathological picture of fragilitis ossium shows such marked absence of calcium deposition in bones, we feel, a priori, that irradiated ergosterol, given in sufficient amounts, say 20-25 drops a day, and observed carefully, will be of decided benefit in early and active cases, e.g., in new-borns. Bookman, also Schwarz and Bass showed an increased cal-

cium and phosphorus retention, in active, early cases, when cod liver oil and phosphorus were fed to infants suffering from this disease.

Judging by x-ray pictures, rickets, osteogenesis imperfecta and osteomalacia (whether adult or infantile) show a calcium and phosphate deficiency. This does not necessarily connote a common cause, but it certainly expresses a similar pathological osseous response. This osseous response is only one of degree, mildest in rickets, more severe in osteomalacia, and severest in fragilitis ossium.

In mild rickets the pathology is usually confined to the epiphyseal ends expressing itself as cupping and mouse-nibbled in appearance. If the rickets is severe, the diaphyses are involved also, producing rarefaction and later bending and fractures. In fragilitis ossium and osteomalacia the process is most severe. The use of Vitamine D together with a diet liberal in calcium should be of decided benefit in these diseases, in their active stages.

## THE MESSAGE OF THE JOURNAL

This Journal is designed to carry messages from the leaders of the Medical Society of the State of New York to the members. The scientific department, for example, contains the messages of the leaders in medicine, surgery, and the specialties; the legal department carries the opinions of the legal counsel regarding actual medico-legal cases in which members of the society are involved.

There is space for messages from every officer and committee chairman. The President is establishing a commendable precedent by sending, his editorial comment and message in each issue of the Journal.

cium and phosphorus retention, in active, early cases, when cod liver oil and phosphorus were fed to infants suffering from this

Judging by x-ray pictures, rickets, osteogenesis imperfecta and osteomalacia (whether adult or infantile) show a calcium and phosphate deficiency. This does not necessarily connote a common cause, but it certainly expresses a similar pathological osseous response. This osseous response is only one of degree, mildest in rickets, more severe in osteomalacia, and severest in fragilitis ossium.

In mild rickets the pathology is usually confined to the epiphyseal ends expressing itself as cupping and mouse-nibbled in appearance. If the rickets is severe, the diaphyses are involved also, producing rarefaction and later bending and fractures. In fragilitis ossium and osteomalacia the process is most severe. The use of Vitamine D together with a diet liberal in calcium should be of decided benefit in these diseases, in their active stages.

## UNIVERSALITY OF MEDICAL PROBLEMS

. The problems of medical practice are everywhere the same. The presidents and secretaries of the medical societies of the several states discuss the same problems that are engaging the attention of the physicians of New York State, as any one may see by reading the Department of "Our Neighbors" of this Journal The medical societies of practically every state provide courses in graduate medicine, sponsor campaigns in diphtheria prevention, and cooperate with departments of health. While nearly all are considering popular medical publicity, Indiana and some other states have made it a major activity, and have evolved standard methods for providing the medical education of the people.

The medical profession of New York State has had its own special problem in outlining and delimiting the fields of activities of the medical profession, the departments of health, and the voluntary health agencies. New York has been the headquarters of voluntary organizations which control millions of dollars of endowment funds with which to conduct "demonstrations" in methods of promoting health, but all other states also have felt the influence of the endow-

New York State has also led in health legislation, especially in state aid of local municipalities in their public health work; but some of the western states have gone farther than New York in the cooperation of the Government with local physicians. Five county medical societies in Iowa, for example, contract with the county officials for the medical attention given to the poor.

As the physicians of each state seek the solutions of their own problems, they can find abundant precedents in other states. It has been the policy of the New York State Journal of MEDICINE for several years that about fifteen per cent of each issue shall be devoted to the experiences of other states in the administration of their medical societies.

Although the several states have made great progress in the solution of their medical problems, none has gone nearly so far as England has gone. The English statesmen have given deep thought to medical conditions in their relation to social problems. They developed methods of bringing medical education within reach of the poor years before the governing bodies of the American municipalities recognized the need of such services. Moreover, the physicians of England have cooperated with the Government in evolving methods which will be efficient and satisfactory to both the physicians and the patients. The description of the plans and their evolution will be found in the pages of the British Medical Journal, which is the national organ of the medical profession of the British Isles. Although the English physicians have not yet solved all, or even most, of their medical problems, yet they have advanced much farther than any state of the United States.

Frequent references have recently been made to the reports of committees of the British Medical Association. An abstract of a report on "A General Medical Service" is found on page 866 of this Journal. An abstract of a report on "Hospital Service" will appear in the Journal of August first; and other reports will be abstracted in later issues of this Journal. Preserve these

reports for information and reference.

## LOOKING BACKWARD

# This Journal Twenty-Five Years Ago

Popular Medical Publicity: The eternal question of popular medical publicity was acute twenty-five years ago, as is shown by the following letter from a doctor printed in this Journal of July, 1905:

"As a member, I wish to protest against endorsement of-Ladies' Home Journal. Please see enclosed giving long-distance treatment. For a so-called reputable journal, it is quack-

ery of the worst type."

The clipping which the doctor sent was as

follows:

"Mrs. L.K.T. asks if it is not dangerous to bind a baby's abdomen tightly to prevent rupture, especially after the third month.

Warmth is needed over the abdomen to aid digestion and the wool-ribbed knit band with shoulder-straps will answer this purpose admirably, and also be much more comfortable for baby than a tight flannel binder.

"Doctor C. will, at all times, be glad to answer the questions of Journal readers. Where an answer is desired by mail a stamped and addressed envelope must be enclosed.

The Journal made no comment on the letter and the article. Our own comment is that departments of health today are inclined to classify such advice as hygienic, rather than medical; and that the medical profession seems to approve such advice.

# MEDICAL PROGRESS

The Gastric Functions in Hot Climates .-W. Borchhardt of the Institute for Marine and Tropical Diseases, Hamburg, has made a study of the physiology and pathology of the stomach in natural and artificial hot climates in both man and animals. These studies include the period of acclimation of Northerners. The blood naturally is forced to the surface to meet the demand for heat regulation by sweating, and therefore the splanchnic circulation is depleted. Dogs with gastric and duodenal fistulæ were subjected to sham feeding and it readily appeared that less gastric juice was produced in hot climates. Analogous results were produced by the use of sweating baths in the temperate zone. Passing to human subjects, four volunteer students were tested with trial meals in the hot air cabinet with high humidity. When the stomach contents were siphoned out 21/2 hours later they were found to be poorly digested, with marked hypochlorhydria. The author apparently made no actual tests in the tropics, but has noted that the unacclimated lose their appetite, the stomach being defective in both motility and secretion. Hence the great demand for condiments-paprika, curry, etc, with food. Lacking some such resource stasis would probably result and the half digested food would accumulate in the stomach. The pancreas and intestinal glands are similarly affected, intestinal stasis develops, and the liability to infectious disease is increased. Not only the hotter condiments but ordinary spices and pungent foods are needed to correct this tendency.-Klinische Wochenschrift, May 10, 1930.

The Ultravirus of Tuberculosis.--A. Calmette mentions the discovery in 1910 by. Fontés of Rio that pathogenic particles exist in the filtrates of cultures of tubercle bacilli (apparently only fresh cultures). This discovery apparently passed unnoticed and Calmette did not become aware of it until 1923. Ever since this period he and his assistants have been at work on the problem and, with many other investigators, they have not only corroborated Fontés but have built up a large body of important facts. The ultravirus has been found in many of the body fluids and it is known to pass through the placenta and infect the fetus. The unknown virus can be cultured in special media (vitaminiferous). The toxin which forms in these cultures is not a tuberculin. It tends to locate in the lymphatic, structures and is a group capable of carrying diseases in which the ordinary acid-fast tubercle bacillus is not represented. In another group ultravirus and

the tubercle bacillus are pathogenic, the former constituting the primary infection, for the tubercle bacillus is alone pathogenic. To designate this second group, we may use the term bacillosis. The ultravirus alone is able to produce a great variety of clinical affections, as inflammation of serous membranes, tuberculides, and even acute miliary tuberculosis which is not necessarily, according to Calmette, a bacillosis. The granules may be due to the presence in the blood of the ultravirus. However, it is not denied that a This discovery marks a bacillary form exists. new stage in the evolution of our knowledge of tuberculosis, following the revolutionary discoveries of Villemin and Koch. Calmette is silent as to the discovery in America of pathogenic fatty and carbohydrate extracts of tubercle bacilli, which still further complicates the subject. -Deutsche medizinische Wochenschrift, May 2, 1930.

Dietetic Treatment of Tuberculosis.-W. Gloor of Zürich sums up the results of the Gerson-Sauerbruch-Herrmannsdorfer tuberculosis diet which had been given a setback by inaccurate radio and newspaper propaganda in Germany. The diet consists essentially of marked restriction of salt, reduction of carbohydrates at the expense of protein, abundant raw vegetables and fruits, separate mineralization, and cod-liver oil. Patients take 7 small meals a day and the requirements of cooking technique are great. Specially trained cooks or nurses administer the diet and must know how to vary it to keep the patients' appetite active. Sixteen different spices are used to give flavor to the food and the diet must be continued for many months. In skin and bone tuberculosis without severe general symptoms, patients take to the diet readily, but in many cases of pulmonary tuberculosis there is great difficulty in getting them to accept it. It is the task of the dietician to overcome the loss of appetite. This treatment can hardly be carried out in the home. The author discusses 3 groups of tuberculosis patients. Excellent results are obtained in skin tuberculosis as shown especially in the recoveries from lupus. The second group is concerned with bone tuberculosis and even fistulous cases are seen to improve, although only 50 per cent of positive results are claimed from the diet alone. main interest in the diet is believed to lie in pulmonary tuberculosis. Sauerbruch and associates had treated one group of 116 cases, all of open tuberculosis. In 43 of these the treatment was

too recent for statistics but of the others 35 showed great improvement, with disappearance of bacilli: 20 showed notable improvement; 11 were unimproved, and seven patients died. The experience of other men has not always been as favorable. We have to discount a group of cases in which improvement might have occurred without the diet. It must not be forgotten that the diet of tuberculosis is a very old subject and that the regimen in question differs from some of the older diets chiefly in the restriction of salt. It is extremely difficult to evaluate the significance of alleged consumptive cures. In many patients who might improve in sanatoriums the financial circumstances are too limited to provide for the diet in less favorable environment. The author cites a few cases in which remarkable results were obtained but believes that under such favorable circumstances the exact pathological and clinical type of the disease is of essential significance. For example the fever curve might play an important role. Cases in high altitude sanatoriums do not apparently benefit additionally from the diet. Onestions which are very pertinent for the immediate future are the significance of the alkalinebase element of the diet and the amount of vitamins which it contains. Sauerbruch claims that the diet favors an acidosis which he regards as desirable. The character of the diet likewise suggests that it is rich in vitamins, but both these subjects require further study.--Schweizerische medizinische Wochenschrift, May 17, 1930.

New Data On Vitamin A .- Beth and Hans von Euler refer to the consensus of opinion of investigators that carotin is the most active principle of vitamin A. The author has tested a large number of carotinoid substances for vitaminiferous properties, and also alleged vitamin A preparations for carotin. Some of the latter are clearly not carotin and in all probability owe their activity to some carotinoid. Carotin exerts no antirachitic activity and some preparations of vitamin A behave in this respect, like vitamin D. The subject of vitamin A is becoming increasingly complicated instead of simplified by recent studies. As a growth agent it is but one of many substances, some protein like tryptophan, while some of the hormones, notably the thyroid and ovarian. act to increase growth. All other growth agents are vitaminiferous-notably the water soluble B vitamin which may be a constituent of the others. Carotin was once believed to stand in some close relationship with the chlorophyll of plants, while originally it was regarded only as the coloring principle of carrots, yellow corn, the yolk of egg, cream, etc., and looked upon as practically inert. By eliminating it from the diet of domestic animals these could be made to produce white cheese, eggs with white yolks, etc. Now it has become

one of the most important of biological substances, through its relationship to vitamins.—Klinische IV ochenschrift. May 17, 1930.

Does Liver Substance Benefit the Spinal Complications of Pernicious Anemia?-Dr. H. Lottig of Hamburg states that spinal cord symptoms develop in 80-90 per cent of all cases of pernicious anemia and that authorities differ widely as to whether or not liver treatment is of benefit in this group of symptoms. Some have seen positive results, especially in recent cases. In an attempt to decide this question Lottig has analyzed 13 cases, of which 9 were from Nonne's and 4 from Schottmüller's clinic. In 6 of the author's 9 cases there was improvement in the spinal symptoms and those related to the posterior columns were much more amenable to treatment than those proceeding from the lateral columns. Recent cases are more responsive to treatment than old ones and benefit may not be apparent until the blood has been regenerated. The four cases of Schottmüller are separately taken up. Case 1 in an old man consisted in numbress of some of the peripheral sensations with beginning deafness and urinary disturbance. After 6 weeks of liver treatment the tactile anesthesia and difficulty in feeling and walking, along with the hearing, had improved and the bladder anesthesia had disappeared. The second patient had numerous spinal symptoms and had evidently taken too little liver for their relief. In the clinic under ample liver and massage she improved remarkably but was unable to take the medicine in sufficient doses, so that as before she relapsed but improved again under full treatment. Patient No. 3 progressed to ataxia and weakness of the legs, but under liver treatment could get about without The spinal symptoms of the fourth support. patient nearly disappeared after 3 months of liver treatment, but reappeared when the treatment was intermitted. She was so anemic that a blood transfusion was given along with the liver and the patient showed marked improvement in her nervous symptoms .- Muenchener medizinische Wochenschrift, May 16, 1930.

Emotional Hypertension.—Edward J. Stieglitz presents a study of 8 cases of extreme vascular instability associated with emotional hypertension. All of the patients had normal arterial tension when at rest. The average age was 37 years. The average blood pressure for the group was 126/80 at rest and 173/109 after psychic excitement. The symptoms were quite variable, being referable to the cardiac apparatus, the head, cutaneous sensations, and the respiratory functions. Emotional instability was characteristic of the group. Sexual disturbances were likewise frequent and notable. One factor was common

# LEGAL

# LIABILITY INSURANCE—NECESSITY OF ASSURED GIVING PROMPT NOTICE

By LORENZ J. BROSNAN, Esq. Counsel, Medical Society of the State of New York

Since the majority of the members of the Society either own or operate a motor vehicle, in connection with which they carry some form of insurance, your counsel feels that it would be of interest to the profession to call attention to a recent decision of the Appellate Division in the City of New York in connection with the necessity of giving prompt and proper notice to the insurance company after the happening of an accident.

In the case to which reference has already been made, the plaintiff brought an action seeking reimbursement from the defendant insurance company for a sum expended in the settlement of two actions brought to recover damages by reason of plaintiff's negligent operation of an automobile. Such settlement was effected after the defendant had refused to defend the actions. Its refusal was based upon plaintiff's alleged breach of a condition in the policy which required immediate notice of accident.

The facts in the case disclosed that the plaintiff owned two automobiles, one a touring car being covered by defendant's policy issued in September of 1922. At this time and until March of 1923, the plaintiff's other car, a sedan, was covered by a policy in the X insurance company. On the latter date coverage on both cars was transferred to the defendant's policy. Subsequently the sedan was involved in the accident out of which the actions arose.

Through inadvertence and mistake, the plaintiff gave prompt notice to the broker who had secured the first policy on the plaintiff's sedan car. This broker in turn gave prompt notice to the X insurance company, and when the actions were begun the plaintiff delivered them to the same broker, who again in turn sent them to the X insurance company, which said company retained them for about three weeks before it was discovered that its policy no longer covered the risk. On that day the defendant company for the first time, and after a lapse of twenty-six days, received notice of the accident.

The policy which the plaintiff had with the defendant company contained the following provision with reference to giving notice of accident:

"In the event of accident the assured shall give immediate written notice thereof to the company, and forward to the company forthwith after receipt thereof every process, pleading and paper of any kind relating to any and all claims, suits and proceedings. The assured shall give to the company full cooperation, and when ever requested by the company shall aid in securing information and evidence and the attendance of witnesses and in prosecuting appeals."

The Appellate Division held, by a divided court, that there must be judgment for the defendant insurance company since the plaintiff had failed to comply with the clause above quoted. In so holding, the court said:

"'Immediate notice' under this clause is notice within a reasonable time under all the circumstances, \* \* \*. In \* \* \* (citing a case), which is among the latest utterances of the Court of Appeals upon the precise question, it was held that a delay of twenty-two days was unreasonable in the absence of explanation or excuse. In \* \* \* (citing a case) a delay of ten days was held, in the absence of proper explanation, to be unreason able as a matter of law. \* \*

"Here the plaintiff had notice of the accident on the day of its occurrence. The only excuse or explanation offered is that through his inadvertence and mistake notice was sent to the wrong company. No claim is made that he did not know of the change of coverage from the \* \* \* Company to the defendant. His failure to notify defendant was due to his own forgetfulness or negligence. In these circumstances we are constrained to hold that he has not sufficiently excused or explained his delay."

One of the Judges of the court dissented from the majority opinion, holding that on the facts above stated the plaintiff was entitled to judgment.

The dissenting opinion is a most interesting one, the learned Judge saying among other things:

"Where, as here, the plaintiff with due diligence gave immediate notice to the broker and the latter inadvertently forwarded the notice to the company who had previously written the insurance, instead of the defendant, the latter cannot plead such inadvertant default to avoid its obligation to the plaintiff in the absence of any change of position or prejudice. It is a well established principle that where a loss has cocured under a policy of insurance and a right to payment ac-

LEGAL 861

crues, provisions of the policy relating to requirements after the loss must be construed liberally with a view to avoiding, it possible, an excusable forfeiture \* \* \*. In the foregoing case, where there was a delay of twelve days, and the position of no one was shown to have been changed to their prejudice, Judge Crane, writing for a unanimous court, said: "The position of no one was changed in the meantime \* \* \* What reason is there for placing a narrow and strict construction upon the words 'immediate notice of loss?" When we consider that this is not made one of the conditions which voids the policy, but is linked up to those provisions relating to requirements after the loss, we should give this policy a reasonable interpretation and a fairly liberal construction. Such is the law A liberal construction always obtains with reference to the procedure after loss \* \* \*. The fire occurred; there is no fraud; the loss has been sustained; the policies covered the loss, and this point relates to those things which must be done by the insured in connection with the remedy. He must give immediate notice of the loss, which we have held repeatedly means notice within a reasonable time. \* \* \*

"In the case at bar, as soon as the mistake was discovered and within a period of twenty-six days the defendant was advised of the loss. There is no claim of change of position or prejudice by the delay. This is not a case of deliberate default If such were the case relief would not be afforded by the courts, \* \* \*. Here the plaintiff having shown a reasonable excuse for the delay in the giving of notice to defendant, and the latter not having changed its position or been prejudiced, the plaintiff is entitled to judgment in accordance with the submission."

Unless, of course, the plaintiff takes the case to the Court of Appeals and that court should reverse the ruling of the Appellate Division, the majority opinion of the Appellate Division represents the law. In any event, the case illustrates the necessity for careful attention on the part of the policy-holder in a situation of this kind, to see that prompt notice is given to the insurance company.

## INFLAMMATORY REACTION FROM THE USE OF PICRIC ACID

In this case the plaintiff called at a hospital clinic for examination and treatment. The plaintiff was examined by the physician in charge of the clinic, who made a diagnosis of pharyngitis' and 'turned the plaintiff over to one of the assistants at the clinic, recommending that blood be taken for a Wassermann test.

The patient was taken to one of the treatment rooms where his arm was bared. Before inserting the needle, the associate physician, not finding the requisite alcohol for the purpose of sterilizing the site for the injection of the needle, used a bottle labelled "2% Picric Acid." The patient immediately complained of pain and a burning sensation at the site of the application, and the location immediately became red.

The doctor then bared the other arm, sterilized a portion above the elbow with iodine, made the necessary injection and drew into a syringe a sufficient amount of blood for the purpose of a test. By this time the first arm had become quite red and swollen. A vaseline dressing was applied and the patient was advised to return for the purpose of treatment for the arm and to ascertain the result of the Wassermann test. Thereafter the patient

did return on various occasions for a period of three weeks. He received surgical attention for a slight sloughing where the arm had shown the reaction to the pieric acid,

On the occasion of such subsequent visits, however, he did not see the Chief Surgeon of the clinic who had first examined him, nor the associate surgeon who had applied the picric acid.

Thereafter, the patient began an action against the Chief Surgeon of the clinic and the hospital where the clinic was maintained, charging that the defendant hospital was negligent in failing to give the plaintiff sufficient and proper medical attention and further charging that the said hospital permitted the plaintiff to be treated by negligent and incompetent employees, contending that both physicians were employees of the defendant hospital. After permitting the action to lie dormant for a long period of time the plaintiff finally voluntarily discontinued the action, upon it being established that the defendant hospital was a charitable institution, thereby terminating the action in favor of both the defendant hospital and the defendant physician without a trial.

# CLAIMED NEGLIGENCE IN THE REMOVAL OF BROKEN NEEDLE

In this case, a needle became imbedded in the plaintiff's thumb during the course of his employment, which needle broke.

He was referred by his employer to the defendant physician who took an X-ray picture, which showed a piece of needle about one-quarter inch from the distal end. The defendant physician then sterilized the surface of the thumb, took a sterilized needle and injected neocaine into the lateral side at the level of the distal end of the proximal phalanx, thereby desensitizing the area where the broken needle was shown to be. The physician then made a slight incision, and with his forceps pulled out the needle shown by the X-ray. One suture was then inserted, the wound bandaged and the patient sent home.

The patient returned the next day, and the wound was dressed with dry sterile gauze. returned two days later, and the same dressing was applied. The day following, the wound appeared to be healing nicely and a similar dressing was applied. The patient returned the next day, the bandage having been previously removed and the suture taken out by someone other than the attending physician. A slight redness of the lateral aspect of the thumb was noticed. The patient said that he had consulted another physician who had treated the thumb, but the nature of the treatment was not disclosed. The defendant physician then dressed the wound with a solution of chlorazene, and prescribed chlorozene tablets to be dissolved and the bandage to be moistened

occasionally. The patient continued to return on each alternate day thereafter for one week, and on each occasion the wound was dressed.

About a week after the removal of the suture, a slight ulcer was noticed on the surface of the thumb. For the next five days the same treatment and dressings as previously were applied. On the day following the last of these treatments, the defendant physician was called to the plaintiff's home. By that time the patient had developed a cellulitis of the thumb without any definite localization. He was then ordered to the hospital to be operated upon the following day, but the patient did not go and the defendant physician never saw the patient thereafter.

Since the plaintiff had been injured in the course of his employment, he had continued to receive compensation for his injury. Subsequent to his treatment by the defendant physician, an action was instituted charging that the defendant had negligently operated for the removal of the needle from the plaintiff's injured thumb and that the said operation was performed without consent, causing the plaintiff to suffer extreme pain, injury and damage. The answer contained the defense that the plaintiff had been fully compensated for his injuries by the awards made by the Workmen's Compensation Bureau. In consideration of this defense the plaintiff ultimately discontinued the case, thereby terminating the action in the doctor's favor without a trial.

## CLAIMED NEGLIGENCE IN FAILURE TO DISCOVER CARBUNCLE ON NECK

In this case, the plaintiff had several times visited the defendant physician for minor ailments, and on a certain date came to the doctor's office complaining of trouble with his neck. The doctor examined the patient and found an infection at the back of the neck which he opened, and a little pus emitted. He placed a gauze bandage on and sent the patient home, and repeated this procedure for each of the next five days, renewing the dressings.

On the sixth day, he was called to the plaintiff's home and found him up and about, but complaining that he was unable to get to the defendant's office. The doctor says he found the neck in about the same condition and repeated the dressing. The doctor called on the man daily from that time up to the 11th day subsequent to the original visit to the doctor's office, each time repeating the dressing.

On the eleventh day, the doctor saw that the infection was spreading and the condition was worse, and he recognized that the man needed radical aid which the doctor states he did not feel

competent to give him, so the doctor put him in a closed car and hurried him to a surgeon's office. From what the surgeon states, he found the man suffering from a very large carbuncle extending over the entire back of the neck. The surgeon put the man in the hospital, and on the following day operated, cutting out the carbuncle which had spread the entire distance across the back of the neck. He kept the man in the hospital for four weeks, and then for two months afterwards the patient went to the surgeon's office and had dressings done, after which time the opening in the neck healed and the patient got well.

The physician's bill was readily paid.

The defendant says that he did not recognize the patient's condition as a carbuncle at first, and the surgeon says that mistakes of this kind are often made by ordinary practitioners.

Suit was commenced, but about two and onehalf years subsequent to the joinder of issue by the service of an answer, the plaintiff consented to discontinue the action.

# LONDON LETTER

Advance of Science: Sir Arthur Keith, the leading anthropologist, Curator of the Hunterian Museum at the Royal College of Surgeons, in delivering the Annual Oration to the Medical Society of London, chose for his theme the "Inexorability of the Law of Evolution." He compared the 120 specialists constituting the Harley Street area of 1880 with the 954 of 1930 and argued that the advance of science with its ancillary sciences, chemistry, physics, pathology, physiology and biology, had called into being a new race of specialists, for the eight-fold increase of specialists contrasted markedly with the mere doubling of the medical population of London in these fifty years. Sir Arthur pointed out that the same process was at work in our hospitals and medical schools. No longer was the teaching done solely by the medical and surgical staffs, but this work was undertaken by an army of experts and organized teams. The "laboratory idea" was displacing bedside teaching. Fifty years ago research was undertaken by a member of the medical or surgical staff who "to gain his end, was willing to offer up his wife and family as an economic sacrifice." He was an amateur, however gifted, and progress demands his replacement by the professional. The effect perhaps is to deprive our teaching branches of some of their most gifted investigators, who prefer to devote their whole time to research, and this tendency to exalt research above teaching may well do as much to impede the progress of medicine as to accelerate it. And just as specialization must increase, so, by the laws of evolution, must unification increase in medicine. "It was the same law that transformed a brood of discrete independent protozoa into the co-ordinated complexity of cells which form the body of a living animal." instanced the progressive interest assumed by the Government, starting with the National Insurance Act of 1911 and passing on through the medical inspection of schools, the anteand post-natal services, down to the most recent legislation whereby the Municipal hospitals are placed under one Central Authority. "However much we may regret the loss of personal liberty, we cannot escape State Control in the long run,"

This was Sir Arthur Keith's conclusion and many agree with him. That a national medical service might come into being owing to a gradual enlargement of the scope of Government control is obvious, and so insidiously do these changes take place, that the profession

may hardly realize it until it is done. It is sad to contemplate that the greatest of all professions may, owing to its very virtues be mechanized and controlled; but we possess a knowledge which is essential to the national life, and in the present temper of public opinion this knowledge should be available equally to rich and poor. We must be prepared to fall in with a system which makes our knowledge available to all, while doing our best to safeguard research and the teaching of medicine.

Annual Meeting Missions to Scamen: The

Prince of Wales, presiding at the seventyfourth Annual Meeting of the Missions to Seamen, expressed a hope that all Societies with similar aims and aspirations should join together to avoid overlapping and obtain greater efficiency with economy. This suggestion coming from so high a source, is sure to receive the most careful consideration. There is one difficutly only to surmount, but it is a very serious one. It may be summed up in two words-pride and jealousy. A cynic said that all Charitable Organizations were started originally by someone who wanted a job as paid secretary. However dubious their origin, the organizations have in the course of time collected round them a body of people, some of whom get their living out of them, while to others they are a source of legitimate pride, and indeed have become one of the real interests in life. Both parties may well view with the gravest concern the submerging of their pet scheme in some great and soulless organization. But if amalgamation would lead to economy and a decrease of overlapping, our Voluntary Hospitals might well be interested. In London each hospital raises. its income from many sources, suscriptions, payment by patients, including grants for work done by such organizations as the Hospital Savings Association and other forms of Insurance, grants from the King Edward's Hospital Fund, payments by local authorities and so on. But it is not easy, nor is it made easier by the fact that each hospital is competing with the others. In some towns such as Leeds and Sheffield the hospitals combine so far as collecting their revenue is concerned, with the result that nearly £9 500,000 is raised every year throughout the provinces for the hospitals, which generally show a balance on the right side. J. M. CARSON, F.R C.S.

# **NEWS NOTES**

# AMERICAN MEDICAL ASSOCIATION

The eighty-first Annual Convention of the American Medical Association was held on June 23-27, 1930, in Detroit, Michigan. The Medical Society of the State of New York was represented by its full representation of fifteen delegates as follows:

A. J. Bedell, Albany
Arthur W. Booth, Elmira
John A. Card, Poughkeepsie
Thomas C. Chalmers, Richmond Hill
Daniel S. Dougherty, New York
Frederick H. Flaherty, Syracuse
J. Richard Kevin, Brooklyn
Samuel J. Kopetzky, New York
George A. Leitner, Piermont
Grant C. Madill, Ogdensburg
James E. Sadlier, Poughkeepsie
Harry R. Trick, Buffalo
Nathan B. Van Etten, Bronx
James N. Vander Veer, Albany
Orrin S. Wightman, New York

The New York Delegation was represented on the ten reference Committees with two chairmanships,—Dr. Grant C. Madill on the Reports of the Trustees and the Secretary, and Dr. T. C. Chalmers on Miscellaneous Business. The delegation was also represented on four other reference committees—Dr. Arthur W. Booth on Medical Education; Dr. J. N. Vander Veer on Constitution and By-Laws; Dr. N. B. Van Etten, on Reports of Officers; and Dr. Arthur J. Bedell on Credentials. Thus out of fifty reference committee assignments, six went to New York delegates.

One hundred and thirty-three physicians from New York State registered on the first day of the session.

The tentative programs of the Scientific Sections, which were printed in the A. M. A. Journal of May twenty-fourth, listed 298 papers, to be presented by 343 authors, and discussed by 103 other doctors. The number of authors from New York State was 48, or 14 per cent of the whole number; while the discussors numbered 23, or 14.5 per cent of the total. While a casual reading of the program might seem to show that New York State was not well represented on the program, yet the fact is that New York with fifteen delegates, or exactly 10 per cent of the delegates from the State societies, had 14 per cent of the scientific papers.

The business of the American Medical Asso-

ciation, like that of the Medical Society of the State of New York, is transacted in the House of Delegates whose minutes are being published in the A. M. A. Journal, the first installment appearing in the June 28th issue. But physicians generally will have an immediate interest in the special features which are reported in the daily newspapers. The Detroit Free Press and the Detroit News made special efforts to secure and publish accounts of those actions which have a wide appeal to the medical profession and to the public. The impressions given by the accounts in those two newspapers are probably as correct as those which would be given by any physician attending the sessions, for the reporters obtain their information directly from the officers or the speakers. The following abstracts were taken from the two newspapers.

Pension Bill:—The News of June 24 says: "Criticizing provisions of the liberalized World War Veterans' Pension Bill as 'without basis in the science and art of medicine,' the American Medical Association, through a resolution adopted by its governing body, the House of Delegates, today came to the support of President Hoover in his fight on the measure.

"The resolution attacks provisions of the bill enlarging hospital facilities at the command of the Veterans' Bureau as 'unsound and socialistic in character.' The duty of providing medical care for veterans disabled by diseases or injuries not of service origin is the duty of the states rather than that of the Federal Government, the resolution maintains."

Sheppard-Tower Act:—The News also said: "Resolved, that the House of Delegates of the American Medical Association condemns as unsound in policy, wasteful and extravagant, unproductive of results and tending to promote communism, the Federal subsidy system established by the Sheppard-Towner Maternity and Infancy Act, and protests against a revival of that system in any form."

Inaugural Address:—The News gave over a column to the inaugural address of President W. G. Morgan and said:

"He referred to the experience of Germany and England in their experiments in compulsory health insurance, under the pressure of growing paternalism.

"'Physicians who lend themselves to such a

scheme, having to see from 90 to 100 patients a day, cannot exist under such circumstances.

"There is nothing inspiring in the thought that the "people"-by which term it cannot be contended that the better elements of our citizenry are meant-must be catered to at the expense of a dignified, self-respecting and selfsustaining part of the population.

"'I do not believe the "people" will be responsible if the time ever comes when the medical profession supinely falls into the lockstep ranks of state-controlled servants. It will be the fault rather of blatant propagandists within our own ranks, operating through unthinking sentimentalists, political tricksters, and noisome newspapers.

"'It cannot be denied that the great middle class of our citizens-the men and women of moderate means, of intelligence, of self-respect, and of carnest purpose who constitute the backbone of our government—have long faced the problem of the high cost of illness and hospital care. But how much of this high cost may be laid on the physician, particularly on

the great rank and file of our profession, the bedside physicians?

"Dr. Morgan granted that certain health measures, such as epidemiology, sanitation. and the care of the mentally diseased, the tuberculous and the indigent sick, require governmental supervision, although they involve more

than prevention

"'But we are not willing,' he said, 'to accept the view expressed by some that public health or preventive medicine has practically no limits. We are not willing to see the entire population, with the exception of the rich, taken away from the individual physician and turned over to the salaried physician, who, by virtue of the circumstances under which he must render his service, will not be able to devote to the individual patient the careful study that is or may be required. And when I say that we are not willing to see these things come to pass, I have in mind the interests of the sick and not the bank account of the physician.' "

Scientific Exhibits:-The exhibit of broken bones impressed the News reporter, for he

"Broken bones are being featured in this, the eighty-first annual convention of the American Medical Association.

"Dr. Paul Nicholas Leech, director of the scientific exhibit, believes there is something resembling poetic justice in the fact that the doctors of America are emphasizing broken bones in their visit to Detroit. An increasing number of fractures has been the result of an intensified industrialism of which Detroit is symbolic, he says.

"Detroit means automobiles to the American Public, and the mention of automobiles brings to the physician visions of an illimitable pro-

cession of plain and fancy fractures.

"This year the great scientific exhibit in the drill half of the Masonic Temple is emphasizing broken bones. In a long series of booths a small army of 75 volunteer physicians are working alternately and continuously upon a group of athletic-appearing young men models, or patients.

These young men are supposed to develop any one of a variety of the most complicated fractures upon a moment's notice. The attending physicians thereupon plaster them, wrap them and swing them in the most approved modern fashion, while little groups of visiting physicians look on and ask searching questions about the technic employed"

Medical Examination of Automobile Drivers: The Association also discussed the subject of Medical Examinations for auto owners' licenses, and according to the Free Press of June 25, it suggested the following plan:

"Each county shall have a licensing board composed of physicians, to be appointed by the Governor of the state, and to be paid by fees from the applicants or by state salaries.

"All applicants shall present a physician's

certificate of physical fitness

"The board shall examine all persons brought to them for physical license; shall pass on the fitness of all applicants about whom individual examiners may be in doubt, and may qualify an exception to be made.

"All applicants must have vision up to a certain standard (minimum of 20-50 in one eye. and 20-100 in the other, with or without glasses). Double vision shall disqualify."

Medical Centers:-The Free Press of June 24 gave considerable space to the policies of the A. M. A. as outlined by the President and the President-elect, and said:

"Several definite proposals for changing the physician's status for his own and the public's betterment were made at the initial meeting of the house of delegates. Most startling was President Harris' that county medical societies establish public centers for the treatment of patients unable to pay full charges, 'These centers would take the place of the present free centers established in many cities, and, being under control of the doctors, would be far preferable to state-owned, or charityendowed institutions' he said.

"'Medicine is being besieged on every side by forces that are becoming stronger and stronger, and unless some defensive effort is made the profession must eventually capitulate and become socialized and become employes of the state,' he declared.

"The establishment of these pay medical centers will do much toward maintaining professional independence of thought and action, and it is infinitely better to do these things voluntarily than to be forced to yield to coertion."

The principal features of the plan proposed by Dr. Harris are included in the address which was given by Dr. Harris before the Medical Society of the State of New York and which is published on page 823 of this Journal.

Principles of Hospital Service:—The Free Press also gave an excellent summary of the address of President-elect Morgan, who proposed the following statement of principles:

"1. The physician is no more obligated to provide for the care of the indigent sick than

his fellow citizen.

2. In mutual charitable undertakings for the care of the sick, each citizen contributes what he has,—the layman, physical necessities;

the physician, professional skill.

3. When a hospital offers its facilities to a mixed clientele, pay, part-pay, and pauper, the distinction between the sources of those facilities should be clearly recognized. The physical equipment and service of a hospital are of general public origin, and their uses may

be sold or given away in the discretion of lay boards; but the professional facilities are, and always must be, the contribution of the medical staff as individuals, and cannot become, in any sense, the property of the institution.

4. When a hospital is owned and operated by government, and supported by taxation, to which the medical profession contributes its due proportion, medical attendance should be paid for by taxation, along with all the other

facilities supplied by the institutions.

5. No hospital, instituted and supported by public philanthropy or community cooperation of any kind, should be permitted to increase its revenue, and so reduce its financial burden upon the public, by any system of collecting fees for medical attendance, and thus engaging in the corporate practice of medicine.

of, the membership of the association should be guided by these principles in accepting posts on the staff of hospitals, and should refuse to support by the contribution of their services or by the references of their patients,

any institution violating them."

Detailed descriptions of the proceedings of the convention will appear in the current issues of the Journal of the American Medical Association.

# A GENERAL MEDICAL SERVICE FOR ENGLAND

The Council of the British Medical Association has made an extensive study of the whole medical situation for England and Scotland, and has made a report which is printed in a supplement of the *British Medical Journal* of April 26, 1930. This report covers sixteen pages and contains proposals for a complete general medical service for the nation. It is exceedingly well written after the manner of the best English publications. Not only is it entirely logical, but its diction is clear and simple and easily understood.

The medical service which it proposed is an extension of the present National Health Insurance Acts system, which, in this country, is popularly called "health insurance." It contains no criticism of the health insurance system; but, on the other hand, it assumes that the present plan, so far as it goes, is satisfactory both to the insured and to the physicians. It sets forth plans for extending that service to include all other people who are not entirely independent financially. It is of special value to the physicians of New York State who are now studying the means of bringing efficient medical service within the reach of all classes of persons. While New York has taken up this matter only within the last two or three years, the physicians of England have studied this problem for a quarter of a century in all its phases, and have developed some well-considered principles which apply equally well to New York State.

The report contains seventy-three numbered paragraphs which are further subdivided for ease of reference and for logical development of the subject. It states eight fundamental principles, as follows:

1. A satisfactory system of medical service must be directed to the prevention of disease no less than to the relief of individual sufferers.

2. The medical service of a community must be based on the provision for every individual of a general practitioner or family doctor.

3. A consultant service, and all necessary specialist, and auxiliary forms of diagnosis and treatment should be available for the individual patient, normally through the agency of the family doctor.

4. The interposition of any third party between the doctor and the patient, so far as actual medical attendance is concerned, should be as limited

as possible.

5. As regards the control of the purely professional side of the service, the guaranteeing of the quality of the service, and the discipline of the doctors taking part in it, as much responsibility

as possible should be placed on the organized medical profession.

- 6. In any arrangement made for communal, or subsidized, or insurance medical service, the organized medical profession should be freely consulted from the outset on all professional matters by those responsible for the financial and administrative control of that service
- 7. The medical benefits of the present National Health Insurance Acts should be extended so as to include the dependents of all persons insured therein.
- 8. Every effort should be made to provide the medical and nursing service faculaties in institutions (home hospitals) where the family doctor may treat those of his patients who need such profession, and who can thus remain under his care.

The report is principally an amplification of these eight principles. It is based essentially on numbers two and three,—that medical service shall be given through the family doctor so far as is possible, and that all other service shall be auxiliary to him. As a matter of fact, it would seem that the success of the present National Health Insurance plan depends on the free choice of physicians by the patients.

The introduction to the report gives a brief outline of reasons for making it, and says that in the last twenty years at least seven factors have increased the attention which the public has given to the subject of health:

- 1. Medical inspection of schools.
- 2. National health system.
- 3. The ministry of health.
- 4. The devastating influenza epidemics.
- 5. The maternity and child welfare schemes of medical authorities.
- Public inquiries into different aspects of the question.
- 7. Increasing interest in the subject taken by the press.

The report states that the British Medical Association has studied the outline of the question with the object, 1, of eliciting the views of physicians, and, 2, of focusing these views into practical schemes. The Association now submits a coherent and inclusive scheme of medical service based on the seven basic principles which have been already stated. The Association believes that its scheme will provide the community wth a service which is, 1, available for every class of population; 2, comprehensive enough to cover the whole field of preventive and curative medicine; and, 3, sufficiently elastic to permit of further development. It refers to a statement in a pamphlet in 1918, which said: "The system of medical prevention which the ministry of health should seek to establish is one which would give to all who are in need of it

every kind of treatment necessary for the cure and alleviation of diseases, and would utilize for this purpose every class of medical practitioner." This principle has been stated by the New York STATE JOURNAL OF MEDICINE as: "All forms of medical service for all classes of people."

The introduction to the report goes on to say: "The scheme may be compared to a plan submitted by an architect to a householder who wants to extend the house in which he lives and to introduce all modern improvements householder may on seeing the plan decide that it would cost too much, and that he must put up with his house as it is, or he may make suggestions for the amplification of the plan. But the householder knows that if he wants to extend his house, he is, as regards the essentials, in the hands of the architects and builders. public may be assured that the architects' scheme here presented is putting forward something which they believe complete and adequate for its purposes; which they think is financially within the collective means of its prospective users; and which can be added and adapted to the extensive constructor with great advantage. The plan has the advantage which a great many schemes from time to time presented to the public conspicuously lack, namely, that it is in accordance with the beliefs and traditions of the medical profession, and would have its wholehearted support."

New York physicians, reading this statement of the support of the medical profession, must remember that the National Health Insurance plan has been in operation in England for a sufficient length of time to have become adapted to the needs and methods of the family physician.

The second part of the report deals with the kind of service required. It states the first elementary principle that medical service must be preventive as well as curative. Such prevention is promoted by various agencies, among them being, 1, the individual patient or head of the family; 2, the family doctor; 3, the public schools for the education of children; 4, public health authorities and voluntary agencies chiefly by health propaganda; and 5, the regular organized public health service.

Commenting on these principles, the report says: "Doctors have their responsibilities and do not wish to shirk them; but it must be recognized that progress in the prevention of disease is much more dependent on the education of the people, on action by the government and by local authorities, and by self control on the part of individuals, than upon any action by doctors. The medical profession can provide the necessary instruction, but it depends on others whether that instruction is put into practice."

The report then goes on to a discussion of the medical services required for the treatment of diseases, which is embodied in the second principle enumerated above. It emphasizes that the family doctor is distinguished from the specialist as the real guardian of health, and devotes a whole page to the relations of the family doctor to the specialist and the consultant.

Included among specialists are pathologists, bacteriologists, x-ray workers, láboratory technicians, and other experts in technical lines. A complete medical service will include profession for all these classes of service which will be given through hospitals or medical centers.

The report also lists auxiliary helpers which will be required such as nurses, mid-wives, ambulances, and an administrative clearing house; and also hospital services of all kinds, including that in dentistry.

The report considers the employment of auxiliaries who give treatments such as physical therapy and massage, and gives the following principles governing their employment:

- 1. "All persons so employed shall have been properly trained and found capable of giving the required treatment;"
- 2. "No treatment shall be undertaken under such auxiliaries except on the recommendation of and under the responsible care of qualified medical practitioners."

Under the head of "Extension of Existing Services," the report considers four classes of patients:

- 1. Those who will prefer to pay directly for all medical service, institutional and non-institutional.
- 2. Those who are able to pay for service in their own homes by a voluntary insurance scheme.
- 3. Those who will be able to obtain home service by a system of National Insurance and also to contribute toward institutional treatment through a voluntary insurance system.
- 4. Those for whom the whole service must be provided without any charge to themselves.

The report emphasizes the principle that every person should pay for medical service according to his needs. About one-third of all the population constitute a class of poor persons who are supplied with medical service through the National Health Insurance. At the opposite end of the financial classification stands that large class who can provide all forms of medical service for themselves. Between these two groups are those members who could provide at least a part of the medical service through some form of voluntary insurance.

The report then considers the provisions for the home care of the patients, including nursing and consulting services, and then discusses at some length the "home hospital," or, what is called nursing home, or private hospital in the United States. The report advocates the construction of nursing homes by the municipalities.

The importance of the general hospital, with its varied facilities for diagnostic treatment, is emphasized in a lengthy paragraph. Pay for all doctors giving medical services is also emphasized.

The report also considers at some length, prenatal care of mothers, infant welfare, and the medical inspection of school children; and also the relation of the Health Department to the whole plan.

The Legislation required to bring the plan into operation would include the following points:

- 1. Extending the present National Health Insurance benefits.
- 2. The incorporation of a national maternity service scheme into the National Health Assurance system.
- 3. The extension of medical benefits to dependants of insured persons.
- 4. The introduction into the National Health Insurance system of the present poor law class for home attendance.

The cost of the extended medical service is briefly discussed and is estimated to be about \$55,000,000 annually.

## APPENDIX

# An Appendix to the report outlines the proposed service as follows:

GENERAL OUTLINE OF SCHEME

The scheme is based broadly on the principles and considerations set out in the foregoing paragraphs, and must be considered in strict connection therewith.

## A. Services Available

- 1. Under a contributory insurance scheme,
  - (I) A general practitioner or family doctor service similar to that provided

under the National Health Insurance Acts and Regulations;

(II) Those services included in the National Maternity Service Scheme excepting the institutional provision which is made by the local authority;

(III) Where recommended by the family doctor:

(a) a consultant and specialist service, both for consultation and for

special treatment when necessary apart from institutional treatment;

(b) a nursing service of visiting

nurses;

(c) such ancillary services as pathological laboratory, massage, x-ray, electrical treatment,

(d) pharmaceutical service for drugs,

medicines, and appliances,

(IV) Dental service, as may be arranged with the dental profession,

Provided by the local authority, for the community generally, and as supplementary to, but apart from the insurance scheme.

(I) When recommended by a medical practitioner and in accordance with the rules of the particular hospital or class of hospital or institution:

(a) residential accommodation and treatment, either in home hospital or special hospital, general hospital or special hospital, maternity hospital, tuberculosis sanatorium, infectious diseases hospital, or convalescent home;

(b) non-residential, for special treatment, other than such as can be included under (1) (III) (a) above.

- (11) Certain ancillary services for children not above school age, as cleansing for verminous conditions, and such routine treatment as can properly be undertaken (subject to general medical supervision) by a school nurse. (Advantage might be taken of the centres where these services are provided to administer certain treatment which it is the duty of a general practitioner or specialist to provide under this scheme where such treatment can be more conveniently carried out at such centres).
- (III) Communal and general health services, as:
  - (a) those known usually as sanitary services;

(b) vaccination;

(c) medical inspection of children not above school age;

dove school age;
(d) educative and non-treatment centres, such as those now known as ma-

ternity and infant welfare;
(e) health education in the schools and otherwise.

# B. Persons Included in the Contributory Insurance Scheme

Compulsory:

(I) All insured persons are defined in the National Health Insurance Acts. (II) All dependents of those insured persons:

(III) Such other persons and their dependants who are so poor that they must be provided for entirely by the community, as may be contracted for by a county council or county borough council, through its Public Assistance Committee.

## 2. Voluntary:

(a) Voluntary contributors, as defined by the present National Health Insurance Acts;

(b) Any other person, not being employed persons, whose income from all sources does not exceed £250 per annum.

(c) Dependants of above-mentioned

persons.

- C. CONTRIBUTIONS FOR PERSONS INCLUDED IN THE CONTRIBUTORY INSURANCE SCHEME
- Weekly premiums paid partly by or for the insured person and partly by the enployer (if any), or wholly by a voluntary contribution.

2. Agreed payments from local authorities under B 1 (III).

A proportion in each case paid by the State.

#### D. Administration

 Central authority—the Ministry of Health (special department); in Scotland the Department of Health.

2. Local authority—the county or county borough council (corresponding bodies in Scotland), provided that:

(I) local authorities might commbine for

this purpose;

 (II) in populous counties with large urban districts a suitable combination of such districts within a county might be constituted an area for this purpose;

- (III) each council must set up a statutory committee, to be called the "Hospitals and Medical Services Committee," which shall be constituted partly of members of the appointing council (so that the Public Health Committee, the Education Committee, the Mental Health Committee,\* and the Public Assistance Committee may all be represented thereon) and partly of the representatives of those bodies of persons who are rendering service under the scheme;
- (IV) all matters relating to hospitals and other medical services not within the reference of other committees of the council shall stand referred to such

committee; and action with regard thereto shall be delegated to such committee, except the power of raising a rate or of borrowing money, the power of appointing administrative officers, and such other matters of a general character as may be reserved by the council with the consent of the Ministry of Health;

- (V) either the chairman or vice-chairman of the committee shall be a member of the appointing council.
- 3. Administrative medical officers: the medical officer of health, together with, in large populous areas, a special assistant medical officer for administrative work.
- 4. (a) A central consultative medical committee, representative of the medical profession, occupying a place similar to that now held by the Insurance Acts Committee of the British Medical Association, whose function shall be to consider matters affecting the medical profession in its relations to this scheme, and to deal with the Ministry of Health in such matters.
- 4. (b) Local medical committees, taking the place of the present Local Medical and Panel Committees, representative of all the medical practitioners of the area; and such other similar committees representative of bodies of persons rendering service as might be necessary, with defined functions.

Under the above council of a county borough might have the following committees dealing with health matters:

- (1) The Public Health Committee, dealing with the sanitary services in the widest sense, with vaccination, with the maintenance and conduct of educative non-treatment centres, and with health propaganda outside the schools.
  - (2) The Education Committee, dealing with health education in the schools, and having a defined relation with school medical inspection and the work of the school nurse.
  - (3) The Hospitals and Medical Services Committee, dealing with all the services named in section A, other than those allotted to other committees.
  - (4) The Mental Health Committee,\* dealing with lunacy and mental deficiency.

(Notes: (a) The Public Assistance Committee would deal with non-medical assistance, and would contract for any required medical assistance where needed.

(b) The Maternity and Infant Welfare Committee might be retained, but would preferably be merged in (3). Blind persons would be aided as regards education by (2), and in other respects by (3) and the Public Assistance Committee).

\* Combining the functions of the present Asylums and Mental Deficiency Committees.

The benefits of the system are summarized in Paragraph 70 as follows:

"There will be a complete coordination of the whole medical service for the community. The family doctor on whom the service primarily rests will be in relation with every hospital in his area and with every medical service provided. He will be able to pass on his patients as they require it to any of the services, non-institutional or institutional, in the area. The hospitals, no longer acting as isolated institutions, their beds and their other services will be so used as to be available as and when necessary for those in need of their services. The medical officer of

health will be able to do his own special work with satisfaction, knowing that for every person in the community there are available all those medical services, for the lack of which much work of the health administration is at present futile."

The more one studies the report the more he will realize its importance and its value to the physicians of New York State.

The report makes frequent reference to a previous report of the British Association entitled "A Maternity Service Scheme," which was published in the Supplement of the British Medical Journal of June 29, 1930, page 258.

# PUBLIC RELATIONS SURVEY NO. 14-WASHINGTON COUNTY

## Population

The population of Washington County is approximately 47,000. There are eight villages in the county, the largest of which has a population of 5,761 and the smallest, a population of 2,100.

# 2. Industries

Farming, paper making, and slate quarrying are the principal industries. There are several shirt and dress shops, one silk spinning mill and one linen thread mill and a number of smaller specialty shops.

### 3 Physicians

There are forty physicians in the county doing active practice

## 4 Hospitals, Institutions, Clinics

There is one general hospital in the county, located at Cambridge, New York. It is rated at 112 beds with 17,198 hospital days for 1929.

There is a Child Health camp situited at Greenwich, New York This camp is open for eight weeks during July and August This is run on the Preventorium idea and takes undernourished children. The children are taken for the full eight week period and will number forty for 1930.

The Great Meadow prison is situated at Comstock and has approximately 1,200 inmates

There is a home for aged females at Greenwich, New York This institution accommodates about twenty inmates

There is a permanent chest clinic at Hudson Falls, New York This operates approximately thirty clinics a year Three hundred and seventy-two patients were examined in 1929. This clinic is equipped with modern a ray laboratories and the examinations are conducted by a salaried diagnostician from without the country. This clinic is supported by appropriations from country and state funds.

Monthly prenatal clinics are conducted at convenient points in the county. They are supervised by members of the state department of health

Orthopedic and mental hygiene clinics are

also conducted by the department of health at regular intervals

### 5 Public Health

Practically every village and town has a health officer with one or two exceptions where health districts have been consolidated Health officers are salaried according to population of their respective health districts

The highest salaried health officer in Washington county receives \$1,000 per annum

There is one county nurse. This nurse is also a director of the chest clinic

State nurses doing prenatal, orthopedic and mental hygiene cover the county very regularly

There are four school nurses employed in the county and compensated by their respective school districts. Their salaries range from \$1 200 to \$1,800 per annum

To my knowledge there is no dental hygienist employed in the county at present

Active tuberculosis is cared for at various

sanatoriums without the county

Immunization against diphtheria has been thoroughly prosecuted in every part of the county

## 6 Organizations

The American Legion and its Auxiliary, the Rotary club, the Elks club and the Women's club with various other organizations throughout the county have taken a very active interest in various public health programs, especially the Child Health camp

Respectfully submitted

M A ROGERS, Chairman Public Health and Relations Committee, June 21, 1930

### HEALTH EXPOSITION IN BROOKLYN

Brooklyn, New York City, is to hold a Brooklyn Public Health Exposition during the week of next October 20, under the sanction and endorsement of the Medical Society of the County of Kings, and the Second District Dental Society Shirley W Wynne, M D Health Commissioner of New York City, Hon Henry Hesterberg, Borough President, Luther F Warren, M D, President of the Medical Society of the County of Kings, and George Crawford Douglass, D D S, President of the Second District Society are Honorary Chairmen of the Exposition

Headquarters for the exhibit which is to be held in the 23rd Regiment Armory, have been opened in the Brooklyn Chamber of Committee Building, 66 Court Street

In connection with the Exposition Borough President Hesterberg has issued a proclamation setting aside the week of the exhibit as Public Health Week. There will be broaderst from one or more of the larger radio stations, messages from the Health Commissioner, The Commissioner of Sanitation, and other speakers equally as well known to the general pubhe

Many concerns are taking space in the exposition These include lines illustrative of the aims of the exhibits such as drugs and chemicals, medicines, orthopedic appliances, exercising appliances, x ray apparatus, first-aid, medicinal and toilet soaps, dental supplies, dental appliances and equipment, health foods, health resorts, sick room supplies, nurses' equipment, professional office equipment and hospital supplies

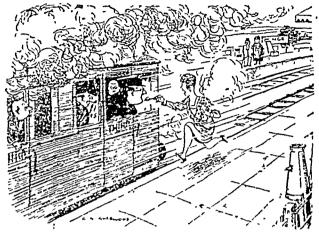

There are 4,000 physiciaus, 3,000 dentists and 2750 retail diaggists in Brooklyn. For these the exposition will be open from 11 \ M to 1 P M daily so that manufacturers may provide demonstrations not offered through the usual channels of merchandising. Fictory, experts and technicians will through this have an opportunity to meet the profession.

# THE DAILY PRESS

# RELATIVITY

From the BROOKLYN DAILY EAGLE of May 3, 1930.

Every event in life has important relations to all other events. Einstein says that if one planet were disarranged from its assigned place, it would start a train of events which would disrupt the Universe. On the same principle, the omission of one's daily dose of medicine after breakfast will utterly ruin that day,-for the wife, at least,-and will start a train of worries which may extend even to the railroad station. The only thing lacking in the cartoon is the family doctor with a look of pained surprise that his patients take his advice with intense seriousness; but possibly he may be one of the couple standing indifferently in the background. Blessed is the doctor whose patients have a deep and abiding faith in him.

## SPACE AND TIME

The Einstein theory of the reality of space and time is a very present actuality to Edward Hope, columnist to the New York *Herald Tribune*, who on June 18 wrote:

"Well, the editors may get all excited, if they like, about Professor Einstein's statement that space is the only reality in the world. It may be a new idea to them, but it isn't to us. We feast our reason upon all sorts of abstractions and allow our soul to flow over and under and around them. And in the end we fetch up at one Fact, space, empty space. Before us every day is Space . . . the space from up here to way down there at the bottom. . . .

"That Space has eaten up Time is no news to us, either. . . . 'When'll you be through?' people ask us almost daily, and we never answer in obsolete terms of minutes or hours. "In,' we usually say, 'about seven inches.'

"Only one man among our friends says that he understands all the theories Professor Einstein brings forward. And now we have a chance to test him on this latest one. We are going to ask him to lunch with us sixteen hundred miles from next Wednesday."

## **BROKEN HEARTS**

An editorial writer in the New York Times of June 28 discusses broken hearts as follows:

"Modern science pursuing its unpleasant practice of lending aid and comfort to superstition, apparently finds Dr. W. J. Mayo sympathetic to the view that maidens thwarted in love may very well have died of a 'broken heart.' He has just told the doctors and surgeons at Detroit that there is good ground for the ancient tradition associating the emotions and the heart. 'Stern control of the emotions throws a strain on the heart.'

"It will be noted that he speaks of injury

wrought to the heart by stern control over the emotions. The myriads of prematurely deceased heroines of fiction and poetry died not from stern control of feeling but no control. It was precisely because they loved too readily and trusted too easily that they paid the price of Lucia di Lammermoor.

"When lovely woman stoops to folly, argued Oliver Goldsmith, her only way out is to die. But by the Mayo doctrine it would be seventeenth-century New England deacons who succumbed to broken hearts as the result of too

firm a hand on the emotions."

#### NOISE AND WORKING EFFICIENCY

The campaign for the abatement of noise which has been conducted by the Department of Health of New York City (See page 573 of the Journal of May 15, 1930) has drawn forth favorable comments from the daily papers. The New York Sun of June 27 makes the following editorial remarks on the good results of noise abatement:

"New recruits volunteer daily in the warfare against noise. Industry is pressed into service because scientists have been able to démonstrate that unnecessary noise means waste. The industrial economist has long known this to be so; studies reported by Ethelbert Stewart, Commissioner of Labor Statistics in the Federal Department of Labor, set, forth the details. Comparative tests indicate that reduction or elimination of disturbing noises often results in greater output and fewer mistakes on the part of workers.

"In one concern where many machines are used, reduction of 28.5 per cent in noise was followed by increase of 12 per cent in output.

Another concern, after moving to a quieter place from a room next to a boiler shop, reported that in the new place 110 units were completed in the time required to complete eighty in the old. A telegraph company, after reducing by 30 per cent the volume of noise in an operating room, found that errors in transcribing messages decreased by 42 per cent and that the average cost of handling a message decreased by 3 per cent.

"These reports are in conformity with recent conclusions reported by Dr. Donald A. Laird, of Colgate University. His experiments showed, among other things, that noise has an inhibiting effect on the normal contractions of the stomach; that outside noises when entering a sleeping room without awakening a sleeper nevertheless raise the sleeper's blood pressure and increase muscular tension.

"Commissioner Stewart suggests that business and industry would find it profitable to give more attention than they commonly do to noise as a factor in reducing the efficiency of employees."

#### FOURTH OF JULY FATALITIES

The Associated Press keeps a record of the Fourth of July fatalities which occur throughout the nation. The New York *Times* of July 6 summarizes the records as follows:

"Apperica paid its price in human life yesterday to celebrate the 154th anniversary of its independence.

"The dead numbered 178. Many other hundreds were injured. Property damage was unusually high.

"Deaths due directly to fireworks totaled twelve. This was the largest number of such deaths recorded in the three years. The Associated Press has been keeping a nation-wide check upon Independence Day fatalities. A year ago there were seven deaths from fireworks. In 1928 there were cleven.

"Automobiles, however, took the most lives eighty-one. In the past three years their holiday toil has increased steadily. In 1928 they took fifty-four lives; last year, seventy.

"There were fifty-seven drownings yesterday, a decline of fourteen from a year ago and of forty-nine from 1928.

"Deaths from fireworks were concentrated yesterday, as in the two previous years, in the New England, Middle Atlantic and Middle Western States. These sections also had long lists of injured. In New York City, where the sale of fireworks is forbidden, 275 persons were treated

for hurns from bootlegged fireworks. At least seventeen persons were seriously injured in Chicago, where celebration of the day with fire-crackers was virtually unrestricted. Chicago had its celebrants who also used firearms and dynamite for their noisemaking; and fire persons were injured by stray bullets. Two were seriously injured by the dynamite.

"In Springfield, Ill., a 77-year-old woman, who was celebrating both her own birthday and the nation's, was seriously injured when a bomb destroyed her home."

Comparative table July 4 fatalities, 1928-1930:

Year	Fire works	Autos	Drown- ings	Other Causes	Total
1928 .		54	106	34	205
1929 .		70	71	11	159
1930 .	12	81	57	28	178
Totals	30	205	234	73	542

The article closes with the following item regarding West Springfield, Massachusetts:—

"Officials of this town of 16,500 inhabitants maintain that the ultimate of safety and sanity was reached in yesterday's Independence Day observance, when a record was set up of no arrests, no fires, no false fite alarms, no fireworks casualties and no motor accidents."

# BOOKS RECEIVED

- Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.
- URO-DIAGNOSTICO DE LA TUBERCULOSIS Y el Cuerpo de Doctrina que le Sirve de Fundamento "La Tuberculo-sis es una Ptomainosis." Por el Dr. Lorenzo Comas y Martinez. Trabajo presentado al 2nd Congreso de la Asociación Médica Panamericana celebrado en la ciudad de Panamá, República de Panamá, Febrero de 1930. Octavo of 103 pages. (Santiago de Cuba, 1930.)
- A Survey of the Law Concerning Dead Human Bodies. By George H. Weinmann. Octavo of 199 pages. Washington, D. C., The National Research Council of the National Academy of Sciences, 1929. Paper, \$2.00. (Bulletin of the National Research Council No. 73.)
- IMMUNITY IN INFECTIOUS DISEASES: A Series of Studies. By A. Besredka. Authorized translation by Herbert Child, M.R.C.S. (Eng.), L.S.A. Octavo of 364 pages. Baltimore, The Williams and Wilkins Company, 1930.
- THE CHILD'S HEREDITY. By PAUL POPENOE. Octavo of 316 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1929. Cloth, \$2.00.
- REFLEX ACTION: A Study in the History of Physiological Psychology. By Franklin Fearing, Ph.D. Octavo of 350 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1930. Cloth, \$6.50.
- THE PRE-SCHOOL CHILD AND HIS POSTURE: A Program of Corrective Exercises Through Games. By Frank Howard Richardson, A.B., M.D., and Winifred Johnson Hearn, B.S. Octavo of 220 pages, illustrated. New York and London, G. P. Putnam's Sons, 1930. Cloth, \$2.50.
- PRINCIPLES AND PRACTICE OF DERMATOLOGY: The Treatment of Skin Diseases in Detail. By Noxon Toomey, M.D. Volume Three. Octavo of 512 pages. St. Louis, The Lister Medical Press, 1930. Cloth, \$7.50.
- Medical Gymnastics and Massage in General Practice. By Doctor J. Arvedson. Translated and Edited by Mina L. Dobbie, M.D., B.Ch. Third Edition. 12mo of 298 pages. Philadelphia, P. Blakiston's Son and Company, 1930. Cloth, \$2.50.
- THE MECHANISM OF THE HEART AND ITS ANOMALIES: Anatomical and Electrocardiographic Studies. By EMILE GÉRAUDEL. Translated, with an introduction by Louis Faugères Bishop, M.A., M.D., and Louis Faugères Bishop, Jr., Ph.B., M.D. Octavo of 266 pages. illustrated. Baltimore, The Williams and Wilkins Company, 1930. Cloth, \$10.00.
- CANCER OF THE BRENCH. By WILLIAM CRAWFORD WHITE, M.D., F.A. 16mo of 221 pages. New York and London, 1 Tanker and Brothers, 1930. Flexible leather, \$3.00.

### BOOK REVIEWS

~ PRACTICAL MASSAGE AND CORRECTIVE EXERCISES WITH APPLIED ANATOMY By HARTYIG NISSEN Fifth Edi tion revised and enlarged by Harry Nissen Octavo of 271 pages, illustrated Philadelphia F A. Davis Company, 1929 Cloth, \$2 50

This is the manual of the Posse Nissen School of Physical Education One part of the book describes the various manipulations and their effects, another part deals with applied anatomy and corrective exercises while a third section goes into the treatment of diseases and injuries which require this form of therapy Flatfoot comes in for consideration. Interesting and authoritative

The Use of THE NEWER KNOWLEDGE OF NUTRITION Foods for the Preservation of Vitality and Health By E V McCollum, Ph D, ScD, and Nina Sim-Monds, ScD Fourth Edition Octavo of 594 pages, illustrated New York, The Macmillan Company 1929 Cloth, \$5 00

The authors of this book stand in the very forefront of the authorities on the subject of nutrition, and it is quite fitting that they should have dedicated their book to Dr C Eijkman who first produced, experimentally, a disease of dietary origin (Beri-Beri) At the time of a disease of dietary origin (Beri-Beri) the appearance of the first edition of this book in 1918, the science of nutrition was in its infancy and no work had more influence in placing the subject on a firm basis than Dr McCollum's investigations Many of the things which, at that time were advanced as comparatively new and possibly unproven are now recognized universally in the field of nutrition

This fourth edition has been brought up to date to May, 1929, with new material regarding anemias both secondary and permicious, dietary requirements for blood regeneration, control of gotter through provision of iodine, the relation of diet to bone development, the calcification of fractures, as well as the prevention of rickets. The physiological effects of light and the changes which it effects in ergosterol are taken up, in addition to

the relation of the diet to Pellagra

While neither of the authors is a physician and while their book is of special interest for the laboratory worker in nutrition, nevertheless, it makes fascinating reading for all those who are in active practice, especially those who deal with the nutrition of the growing child

WM HENRY DONNELLY

GRENZ RAY THERAPY By GUSTAV BUCKY M D Trans lated by Walter James Highman, M.D. Octavo of 170 pages, illustrated New York, The Macmillan Company, 1929 Cloth, \$3 50

The author describes a new ray which rests between the ultra violet and "soft' X ray section of the spectrum adjacent to the latter, and terms it the "Grenz Ray," literally translated meaning a 'border ray"

Its length is about two Angström units, shorter than ultra-violet but longer than the softer X-rays He states since but approximately 10% of X-rays are absorbed by the skin, as against 88% of Grenz Ray, the therapeutic efficacy of the latter for cutaneous diseases is readily apparent.

Much space is given to argumentation defending the author's claim-contradicted by others, but on the other hand, he frankly admits much is to be done before establishing the Ray therapeutically

The well known physicist, Dr Otto Glaser of the Cleveland Clinic, has contributed a chapter on its physics and infers, if he does not actually state, the Grenz to be a very soft X ray

A chapter is given to the treatment of various skin lesions with their end results, but here again, the relative sparsity of material calls for more work before its superiority is convincing. Claim is made for its general effect upon the autonomic nervous system to the end that various endocrine conditions, nay, even duodenal ulcer, c in be improved

Its position in the armamentarium of the Radio-therapist may eventually be established, but for the time being, a conservative viewpoint is probably safest

MILTON G WASCH

THE PATHOLOGY OF THE LYE BY JONAS S FRIEDEN-WALD AM, MD, FACS Octavo of 346 pages illustrated New York, The Macmillan Company, By Jonas S Frieden-Octavo of 346 pages 1929, Cloth, \$4 50

The dearth of works on pathology of the eye makes the ophthalmologist reach out at once for any work on this subject. When the name Friedenwald is signed to such an effort, the interest of the most dormant is en-

sured

The introductory chapter, instead of being burdened with an elaboration of well known anatomical descriptions, is composed of well selected points on significant anatomical and physiological aspects One has a satisfied feeling as each page is turned This is but an appetizer for the feast of pathological pabulum to follow. The text proper seems delightfully lacking in that long drawn out dryness so apt to burden descriptive science only is the diction pleasing, but there is none of that verbosity so apt to clutter a scientific effort. The author's arrangement of the material presents the subject in such a way that the reader may spend a few moments now and then, laying aside the book when interrupted, and yet carrying with him a complete picture of some special entity All through the book one is struck by the writer's very level headed and honest presentation of problems which are usually seen in a very biased light "The Pathology of the Eye" is a real addition to the American Ophthalmologic literature. JOHN N EVANS

CPIDEMIC ENCEPHALITIS Etiology-Epidemiology-Treatment Commission, William Darrach, Chairman 12mo of 849 pages New York, Columbia University Press, 1929

The subject is considered under three headings, etiology, epidemiology and treatment. In addition, a brief

chapter is devoted to a consideration of other forms of encephalitis including Post-Vaccinal Encephalitis. This work fulfills the purpose of The Commission, namely "to collect and tabulate" the work throughout the world on the subject of Encephalitis "so that the collection would be available to all who are interested" The literature has been reviewed critically by Dr Josephine B Neal, Director of The Survey, and her co workers, and a serious attempt has been made by them to evaluate the various manifold efforts particularly in treatment and also the experimental work in etiology A tremendous amount of time and laborious effort must

have been expended in this analytical survey.

However, as can be expected in a book of this scope, little original data has been offered except for a few control of the c hmited conclusions drawn from the accumulated statistes This book serves its intended purpose well and is highly recommended. As a work of reference on the subject of Epidemic Lincephalitis, it is ideal

HARLD R MERWARTH

MODERN METHODS OF TREATMENT. By LOGAN CLENDEN-ING, M.D. Third Edition. Octavo of 815 pages, illustrated. St. Louis, The C. V. Mosby Company, 1929. Cloth, \$10.00.

Easily first among modern classics. Like the younger generation in all things else, it is audacious. As a super-Paracelsus, Clendening puts the medical house in order with gusto and authority. This is the third edition of an engaging work. A wide range of therapy is covered and the reader's interest never allowed to flag. The author succeeds admirably in his most commendable aim so to describe each therapeutic procedure as to make it easy of application by novices. The work combines practicality and scholarship. Seven collaborators supplement the chief author's efforts and the result is a standard work of the highest order.

A. C. J.

MEDICAL LEADERS FROM HIPPOCRATES TO OSLER. By SAMUEL W. LAMBERT, M.D., and GEORGE M. GOODWIN, M.D. Octavo of 331 pages, illustrated. Indianapolis, The Bobbs-Merrill Company, 1929. Cloth, \$5.00.

The author's method in this interesting work is that which divides the gamut of medical history into periods stamped by great personalities. Thus Paracelus, Vesalius, Paré, Harvey, Jenner, Lister, Gorgas, Osler and the other giants are portrayed in relation to their backgrounds and the inevitable evolution of medicine traced down the ages into the living present. Philosophic, economic, social and political factors are discussed illuminatingly and we are made to see that steady growth is the central fact of the great drama. A capable performance which should intrigue the intelligent laity, for whom the book seems primarily intended.

A. C. J.

THE NERVOUS CHILD. By HECTOR CHARLES CAMERON, M.A., M.D. Fourth Edition. 12mo of 249 pages. London and New York, Oxford University Press, 1929.

This is the fourth edition of a work which first appeared in 1919, and which has enjoyed international popularity on account of the commonsense method of handling the subject, as well as the authoritative standing of the author on this particular phase of Pediatrics. Dr. Cameron is the physician in charge of the Children's Department at Guy's Hospital, and it is a Pediatric education in itself to attend his clinics in the out-patient department of that Hospital, in which he treats not only the nervous child but the child sick from whatever cause. It strikes the American visitor as rather remarkable that the head of the Pediatric Department of a great institution should spend hours of his time in the out-patient department examining and treating cases himself and lecturing upon them to both under-graduate and graduate students.

Since the third edition of this book appeared in 1924, it has been thought necessary by the author to add a chapter on the "Underlying Disturbances of Metabolism in the Nervous Child." It is in the treatment of just such cases that Dr. Cameron has achieved a wide reputation and it is also here that his method of the administration of sugar in the form of dextrose at bed time has been of real service. The pale, exhausted, irritable, nervous child inclined to recurrent attacks of vomiting shows, as a rule, blood sugar at a low level, if not a definite hypoglycemia, ketonemia, and a diminution of the alkaline reserve of the blood. In view of these findings, the administration of glucose (dextrose) is founded on a good physiological basis. Such cases must have a restricted fat intake with a proportionately raised intake of sugars and starches. A daily small dose of alkali is found helpful such as a teaspoonful of bicarbonate of soda. By dietetic regulation along these lines and the free administration of glucose and of a small amount of alkali, good results can be obtained; such as, rapid increase in weight, improvement in color and energy.

The previous edition of this book has been so widely read and so favorably received that it would not seem necessary to do any more than merely outline the contents of the chapter which has been added to the present issue.

WM. HENRY DONNELLY.

THE EYE IN GENERAL MEDICINE: The Constitutional Factor in the Causation of Disease with Special Reference to the Treatment of Diseases of the Eye. By A. MAITLAND RAMSAY, M.D., LL.D. Second Edition of "Diathesis and Ocular Diseases." Octavo of 255 pages. New York, William Wood and Company, 1929. Cloth, \$5.00.

The first edition of this small work was published in 1909, under the title "Diathesis and Ocular Diseases." The present edition attempts to represent the original material from a more modern angle.

The reviewer feels the attempt has been only partly successful. We still find the subject viewed through the steel frames and black glasses of 25 years ago.

The word pathognomonic is frequently used together with certain very positive statements about certain little understood processes. This attitude typical when ophthal-mology was finding itself, is of necessity to be discarded in this iconoclastic period. Moreover, a simple recitation of evidence should be more useful. While the author takes this old-fashion method of presentation, it must not be inferred that his book is lacking in modern material. The reference to "sluggish liver" and allied expressions need not detract from our appreciation of the effort. There is a certain homely quality to this old-fashion method of looking at problems ophthalmological which is most pleasing. Perhaps after all, we have but changed the words of the older forms of expression without having a clearer idea of what we mean.

One feels that he is absorbing very valuable bits of very useful information while perusing this little work.

J. N. Evans.

HYGIENE OF THE MOUTH AND TEETH. By THADDEUS P. HYATT, D.D.S., F.A.C.D. 16mo of 64 pages. Brooklyn, N. Y., Brooklyn Dental Publishing Company, 1929.

"Hygiene of the Mouth and Teeth" is an epitome, consisting of sixty-four pages, written by Thaddeus P. Hyatt, D.D.S., one who has considerable experience in the educational fields along these lines. The book has been written especially for the lay public, and brings home the proper health and conservation of the teeth and the importance of a clean mouth and sound teeth.

L. F. CRASSON.

SURGICAL RADIOLOGY. By A. P. BERTWISTLE, M.B., Ch.B., F.R.C.S. Ed. 12mo of 142 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, 1929. Cloth, \$3.50.

This little book of one hundred and thirty-four pages with twenty illustrations is another work on Roentgenology which consists of practically nothing more than an enumeration of the conditions of the human body which may be shown by Roentgen examination.

The chapter on the recognition and localization of lesions of the brain is well written and instructive. As the author states, this is a reprint from an article published in the *British Journal of Radiology* and is evidently a subject to which he has given considerable thought.

The remainder of the book is more or less superficial and is of no particular scientific merit. At times, the author's language is rather ambiguous and further editing would be of value.

This same method of handling the subject has been done before by both American and British authors in a much better way. The few illustrations are good.

AN OUTLINE OF NEUROLOGY AND ITS OUTLOOK Being the Eleventh Earl Grey Memorial Lecture By Sir E Farguhar Buzzard, KCVO MA MD Octivo of 24 pages London and New York Oxford University Press, 1929 Paper, \$35

In this, the Eleventh Earl Grey Memorial Lecture, the author has given us essentially an historical outline of the development of man's knowledge of his nervous system in its various phases beginning with Alemeon and Hippocrates down to Sherrington, Jickson, Freud and Pavlov In all but two of the twenty four pages, he develops his historical sketch through five different paths of approach in the contributions of the anatomist physiologist, clinician pathologist and psychologist. The final one and one half pages are devoted to The Outlook of Neurology," with a baldly frank painting of the true state of Neurology.

The pamphlet is a concise, erudite presentation, remark able for its clarity. It makes genuinely delightful reading. Such a valuable little pamphlet should be in the

possession of every student of neurology

HAROLD R MERWARTH

THE TREATMENT OF THE COMMON DISORDERS OF DIGES TION A Handbook for Physicians and Students By John L Kantor, Ph D, M D Second Edition Octavo of 300 pages, illustrated St Louis, The C V Mosby Company, 1929 Cloth, \$600

In this second edition, the author has added several chapters on Diserses of the Colon One is pleased to review a work of this nature for, as practicing physicians, we are all interested in the treatment of disease. Although the volume has been enlarged, the sequence is uninterrupted. The concise mainier in which the author presents both the subject matter and the questions of therapy will meet with the general approval. In the discussion of Gastric and Duodenal Ulcer, the thoroughness and simplicity of expression make interesting and profitable reading. The book is well illustrated, especially in the chapters on Colon Disorders to which subject the author has made a great many valuable and original contributions. It is a book which should be in the office of every physician for it contains a great deal of information of a practical nature and covers the entire subject.

THE TREATMENT OF FRACTURES AND DISLOCATIONS IN GENERAL PRACTICE. By C Max Page, DSO, MS, FRCS, and W ROWLEY BRISTOW MB, BS, FRCS Third Edition Octavo of 284 pages, illustrated London and New York, Oxford University Press, 1929

The want of a short treatise of this kind has been felt for a long time by the general practitioner. The authors have shown good judgment in the allotment of space to the various fractures and dislocations in proportion to the frequency of their occurrence. A spirit of commendable conservatism pervades through the entire work. The specialist will possibly consider that skeletal traction and open reductions have not been sufficiently emphasized in some cases but the aim of the book as expressed in its title is sufficient justification for the adopted conservatism.

Considered as a whole, the book is thoroughly scientific intensely practical, well written and excellently illustrated

Geo Webb

The Volume of the Blood and Plasma in Health and Disease. By Leonard G Rowniree, M.D., and George E Brown, M.D. 12mo of 219 pages Phila delphia and London, W.B. Saunders Company, 1929 Cloth, \$3.00 (Mayo Clime Monographs.)

Rowntree Keith and Geraghty introduced in 1915 the dye method of determining the plasma and the blood

volume The new principle involved was the direct introduction into the circulation of a known amount of a non toxic, slowly absorbable dye. After remaining in the circulation long enough to be thoroughly mixed (3 to 6 minutes), the concentration in the plasma was determined colorimetrically by a suitable standard mix ture of dye and serum and from the extent of the dilution of the dye, the plasma volume was determined By utilizing the hematocrit values after rapid centrifugalization, the total blood volume was computed and normal values established. The plasma volume was found to be in a normal man approximately 5% of the body weight and the total blood volume 88% of the body weight The authors formerly used vital red but now generally employ Congo red principally on account of its availability

This monograph reviews the subject and adds the results of prolonged experience. A criticism of the dye method with some comparisons to the carbon monoxide method, a description of the technic and a consideration of normal subjects are presented in the early chapters

Studies are reported concerning more than 250 cases of various diseases in which the method was used Among the conditions of much interest are polycythemia vera, leukemia, pernicious and secondary anemia, essent al hypertension, myxedema, obesity and various types of edema as found in glomerulonephritis, nephrosis cardine disease and diabetes mellitus. The largest blood volume was found in polycythemia vera and the smallest in pernicious anemia. It is of interest to note that in essential hypertension no significant increase was found in the blood volume or plasma volume or any disturbance in the relationship of cells to plasma The vascular bed is too small for the volume of blood rather than the volume of blood too large for the vascular system" is of course in accord with prevailing ideas. In cardiac edema high values for both blood and plasma were generally found also in nephrosis but not in glomerulonephritis

The belief is expressed by the authors that 'another milestone has been reached that henceforth in dealing with the blood, concentration studies will fail to suffice and that information concerning total quantities will be demanded in many instances."

This conclusion seems to be justified by the work presented and the method may indeed prove to be a very valuable one in the study of some diseases, the pathogenesis of which is very imperfectly understood

W E. McCollon

Blood Grouping in Relation to Clinical and Legal Medicine. By Laurence H Snyder, ScD Octavo of 153 pages Baltimore, The Williams & Wilkins Company, 1929 Cloth, \$500

This book calls to the attention of the physician the practical importance of the subject which until only recently interested primarily those engaged in the field of genetics and immunology. Only those who have done investigative work on isohemagglutination and have searched the tremendous literature on this subject can test appreciate the masterly way in which the information has been sifted and properly evaluated by the author

The chapters on the Heredity of Blood Groups and its medicolegal aspects deserves special comment. Here the author leaves out nothing of value, although the pages are few In these pages, however, are found the essence of volumes

The subject of blood transfusions is treated in detail

with separate chapters on the history and technique of, as well as the indications for transfusions

The extensive bibliography and clear illustrations are additional features which should make this book extremely popular

#### MEDICAL PROBLEMS IN CALIFORNIA

The May issue of California and Western Medicine contains the Annual address by Dr. M. R. Gibbons, President of the California Medical Association, in which he says:

"The esteem in which we are held as a group has everything to do with proper direction of the changes which many of us think are inevitable.

"The medical profession is the largest educated group with a common interest. It is a highly educated group. It has a very high proportion of good minds; yet, are we respected and do we carry weight in proportion to our mental equipments and attainments? I think not. If not, what are the reasons? I believe that it is because (1) we are not a business group; (2) we submit to exploitation; (3) we do not exhibit cohesion or concert of action; (4) we do not talk the same language as laymen; (5) our code of ethics disconcerts them.

"And now I come to the most important economic subject before the medical profession to-

day—state health insurance.

"All about us are evidences of forces working in that direction; (1) The various federal provisions for wholesale health care, the Army, Navy, Public Health Service, Veterans' Bureau, and all that these embrace. (2) The State and City health machinery. (3) County hospitlas providing medical care at wholesale rates. (4) Employers' hospitals and health service. (5) Workmen's compensation for industrial injuries. (6) Private health insurance and hospital associations. (7) And most of all, the attention focused on the high cost of medical care by the activities of the national committee.

"It will be easy for the people to accept the idea of state health insurance. Insurance is under-

stood and is gaining more adherents every day, due to the supposed efficiency and economy of large organizations. Hence, it will be easy to reason that the independent doctor is inefficient, whereas the medical machine would be efficient. Such reasoning, we know, is not true without important qualifications, but we must be prepared to convince many people. If we exhibit prejudice, we can have little influence in shaping legislation.

"It is customary to consider the California Workmen's Compensation Law to be practically perfect. It is a remarkably effective law and is administered in an enlightened manner. However, in its insurance phase, where the patient-doctor relation comes in, it permits the interposition between the patient and the doctor of a layman, ordinarily without sympathy or knowledge or appreciation of the delicate balance necessary for the best results.

"The production of the traumatic neurosis cases is chargeable in a large measure to this arrangement. There is no means of knowing to what degree this is a fact. My estimate is that one-half of all such cases are precipitated or aggravated by unsympathetic or harsh or misguided handling by laymen. These conditions should be prevented.

"Another objection to lay intervention is that laymen have shown a knack for selection of doctors who are insurance-minded, or are at least pliable. The doctors reflect the insurance company's attitude toward the insured. The fine example of some insurance companies which have enlightened medical supervision shows what is possible."

#### LIST OF STATE MEDICAL ACTIVITIES

The Annual report of the Committee on Medical Economics of the Ohio State Medical Association, which is printed in the May number of the Ohio State Medical Journal, gives the following list of socialized Medical activities now in existence:

"As for 'state medicine' in the several states, including Ohio, there are the accepted and recognized departments and functions of the State Départment of Health, including sanitary engineering, water and sewage control, communicable diseases, hygiene and State De-

partment of Health Laboratory; the function of examination and licensing of physicians and other practitioners, medical education in the state medical school, university hospital and student health service, workmen's compensation, department of welfare with its 23 state institutions, including 11 institutions for the care of the insane, feeble-minded and epileptic wards of the state, as well as the other penal and correctional institutions, bureau of juvenile research, etc., division of health and physi-

(Continued on page 880-adv. xii)

## Dextri-Maltose for Modifying Lactic Acid Milk

In using lactic acid milk for feeding infants, physicians find Dextri-Maltose the carbohydrate of choice:

To begin with, Dextri-Maltose is a bacteriologically clean product, unattractive to flies, dirt, etc. It is dry, and easy to measure accurately.

Moreover, Destri-Maltose is prepared primarily for infant-feeding purposes by a natural diastatic action.

Finally, Destri-Maltone is never advertised to the public but only to the physician, prescribed by him according to the individual requirements of each baby.

DEXTRI MALTOSE NOS 1, 2 AND 3 SUPPLIED IN 1 LB AND 5 LB TINS AT DRUGGISTS SAMPL'S AND LITERATURE ON DEGUISTS MEAD JOHNSON & LO EVANSVILLE IND USA -In Rickets, Tetany and Osteomalacia-

Because of our long experience,
Mead's Viosterol in Oil, 100 D,
does not turn rancid in properly closed containers. We were
first in America to produce pure
ergosterol and also to standardize activated ergosterol. Mead's
Viosterol (originally Acterol) is
admittedly the pioneer that set
the now accepted standards of
safe potency and dosage.

Specify the American Pioneer Product— MEAD'S Viosterol in Oil, 100 D— Mead Johnson & Co, Evansville, Indiana

### "Hold Fast to That Which is Good"

The Mead Policy that for years has proved itself professionally and economically valuable to physicians who feed infants also applies to Mead's Viosterol in Oil, 100 D (originally Acterol). As with Dextri-Maltose, we feel that Mead's Viosterol is a part of the physician's armamentarium, to be prescribed by him alone.

Therefore, we refrain from lay advertising of Mead's Viosterol or any other Mead Product; furthermore, we do not print dosage directions on the bottle, on the carton or in a circular. "Hold fast to that which is good"—the Mead Policy, Dextri-Maltose and Mead's Viosterol (originally called Acterol).

MEAD JOHNSON & CO., Evansville, Ind., U.S.A.

graphs, may be listed free service in private practice, hospitals and dispensaries, as well as failure of physicians to charge for preventive work, immunization, etc. Public health federations, health conservation leagues, parentteachers organizations, state and local, have distinctive socialized functions.

"Other group socialized functions include industrial medicine, insurance examinations and practice, insurance including periodic health examinations, health and accident insurance, railway and public utility medical service, lodge practice, trade union health benefits, life extension institutes, health by mail laboratories, contract practice, group disability insurance, health magazines and even syndicated health literature in newspapers and other lay publications.

"These data are significant. They have been gathered and here expressed, to inform the profession of the wide extent over which medicine has already been socialized and to provoke serious thinking on the possible results

of further extensions.

#### BLUE RIBBON CAMPAIGN IN KENTUCKY

A blue ribbon children's campaign conducted in Kentucky is the subject of the following editorial in the June issue of the Kentucky Medical Journal:

"We have just returned from a trip through Eastern Kentucky where we had the privilege of assisting the County Medical Societies and the County Health Departments in pinning blue ribbons on several thousand children who came up to the standards fixed by joint action of the State Medical Association and the State

Board of Health.

"It is worthy of note that this year, fifty thousand Kentucky children have received blue ribbons. This means either that their eyes, noses, thoats and sinuses, teeth, posture and weight for age conditions were normal or have been corrected to the normal. A careful study in several counties revealed the interesting fact that this has necessitated an average of five trips to the doctors' and dentists' offices for each of them. More than two hundred thousand other children have also been reached in this campaign and have started toward their corrections in the same way.

"Think of what this means in terms of the future of these children. They have been taught, along with other things they are learning, that doctors and dentists are the people who are armed with the scientific knowledge necessary to preserve their health and lives.

The cults that will be devised by quacks in the future will find an army of citizens who have been taught faith in science and who will refuse to be misled.

"The Medical Profession of Kentucky has made no greater contribution to the citizens of the State than in the inauguration and successful maintenance of the Blue Ribbon Campaign. This is but one of the instances of the proud record of our profession to our Commonwealth.

"Armed with these facts physicians can go before the people of the State with a proper pride in their achievements and can easily maintain the leadership that has so long been bestowed upon us in matters pertaining to scientific medicine and Public Health."

#### PUBLICITY BUREAU OF INDIANA

The Indiana State Medical Association has a Bureau of Publicity consisting of four or five members who meet weekly. The meetings of March 25, April 1 and April 8 are printed in the May Journal of the Indiana State Medical Association. The principal business transacted was as follows:

"The material from the director of the Child Hygiene Division of the Indiana State Board of Health asking for and making some suggestions in regard to pre-natal and maternity education in Indiana was discussed by the Bureau.

"The following form letter was sent to 121 editors of newspapers who had not been receiving our releases regularly:

"'For several years the Bureau of Publicity of the Indiana State Medical Association has prepared and distributed free of charge to the newspapers of Indiana weekly bulletins telling of new developments in medicine, giving information upon various diseases, and making suggestions concerning individual and community health.

"These bulletins have been written in language that the average reader can understand and an attempt has been made to make them as interesting and, at the same time, as scientifically correct as possible.

"'In checking over our records we find that your paper is not on our mailing list. If you should desire to have the name of your paper placed upon our mailing list to receive these weekly bulletins, please return the enclosed postcard with the name and address of the person to whom they should be sent.'

"Thirty cards were returned requesting that the articles be sent to these newspapers regularly. Only one editor expressed any feeling against using the material.

(Continued on page 883-adv. xv)

(Continued from page 882-ad 110)

"The meeting of April first took the following actions

"The release, 'Taking the A\ out of La\atives' was read and approved for publication Saturday, April 12

Radio releases from the Marion County Fuberculosis Association were approved for broadcast on the following dates April 5th, April 12th, April 19th, and April 26th

"The Bureau approved the suggestion that the newspaper releases for Saturday, May

10th, be upon National Hospital Day

"The following letter was received from a special representative of the National Food Bureau who recently had visited the headquarters office

"I have just returned to the office and want to thank you for your cooperation and interest in the articles that have appeared in the newspapers, also the special news letter that was sent to the medical profession

"'This is what helps to climinate these food faddists and quacks from preying on the pub-

lic'
"Letter received from an Indiana physician telling of a 'Dr' Frank McCoy who is writing

a health article daily for his newspaper in which opinions are continuously expressed which are not complimentary to the medical profession. This letter was to be referred to the National Food Bureau.

'Article, 'Doctors and Their Ethics' published in Liberty of April 5, 1930, brought to

the attention of the committee

'The minutes of the meeting of April 8 contain the following entries

'The following letter received from the Post and Commercial-Mail at Columbia City, Indiana "'At the present time in this community

there are a number being treated for 'trenchmouth' by local dentists and physicians

"'If you have a bulletin such as we receive weekly through the secretary of the Whitley County Medical Society, telling of this disease and preventive treatment, we feel that by publishing it both the association and the newspaper would be rendering the public a valuable service'

"As a result of this letter the release entitled 'An Unpaid War Debt,' upon trench mouth, was prepared and approved for publication Saturday, April 19th

"May 21st—Indiana Pharmaceuticai Association. Lafayette, Indiana. Matter to be brought to the attention of the Bureau at next regular weekly meeting.

"June 5th—Fountain-Warren County Medical Society, Covington, Indiana. Arrangements completed for speaker.

"The Bureau of Publicity expressed its gratitude for the splendidly efficient work that is being carried on by the Better Business Bureau in ferreting out and bringing to light the misrepresentations of quacks.

"A report received from the Committee on the Cost of Medical Care was brought to the attention of the Bureau and will be considered in detail at the next meeting."

## COUNCILOR DISTRICT MEETING IN WISCONSIN

The common routine of reports of county societies and district branches is relieved in the following report of the Seventh Councilor District taken from the June issue of the Wisconsin Medical Journal:

"The annual meeting of the Seventh Councilor District was held at Sparta on the afternoon and evening of May 13th. Sixty-five members were present.

"The program for both afternoon and evening sessions was put on by Dr. Buerki, Superintendent, and four members of the staff of the Wisconsin General Hospital. The clinicians were Dr. Gonce, Pediatrics; Dr. Burns, Orthopedics; Dr. Gale, Chest Surgery; and Dr. Harris, Obstetrics and Gynecology.

"According to previous contract none of these men presented papers. Each was put upon the "witness stand" for the period of an hour and required to answer any and all questions put to him covering his particular field of work. At the close of the sessions it was the consensus of opinion that each had acquitted himself with great credit. The questions asked covered a wide field and gave all present an opportunity to press questions of personal interest and concern.

"The banquet at the Sidney Hotel was somewhat marred by an unwarranted raid of the banqueters by the Sparta police force. Without warning six of them suddenly closed

(Continued on page 885-adv. xvii)

(Continued from page 884-adv 111) all exits to the dining-room and proceeded to frisk the hip pockets of all present, especially the La Crosse delegation.

"No 'oil' was struck until Dr. Robert Flynn of La Crosse started to jump through a window. Three policemen caught him and after a terrific battle relieved his hip pocket of a half-pint bottle-full of milk and a red nipple on it. He was arrested for carrying concealed weapons.

#### COLLECTION AGENCIES IN WISCONSIN

Agencies for the collection of bills which are owed to physicians frequently seek to advertise in the columns of state medical journals, but from the nature of their work they are likely to be misunderstood by their clients. One point of view is expressed by the following editorial from the June issue of the Wisconsin Medical Journal:

"We have several times referred to the 'ways and means' of collection agencies in these columns. That we carry the advertising of no Wisconsin company is, in itself, evidence of our opinion of such advertising of Wisconsin and Illinois companies as has been proffered for our acceptance. In the past we have more than once pointed out the necessity of studying contracts of these agencies most carefully before signing, regardless of what the solicitor says they contain and mean. That this is most essential may be evidenced by a recent experience of a member in the southern part of the

"Signing a contract for what he thought to be a six months' trial of the services, he finds that two years later the agency claims their fifty per cent on accounts collected by the physician himself a year after the contract supposedly had expired. He wrote the agency pointing out that their contract said 'This agreement to be in force for a period of six months from date hereof except claims in process of collection which shall be released when paid or discharged,'

"The agency calls his attention to the matter which follows the word 'except' and then says 'as long as claims are in our office our work continues. We never quit,' .

"May we again repeat that these contracts have been a source of a very considerable numher of complaints in the office of the State Society. If you believe in the efficiency of these agencies whose advertising you do not find in the columns of this Journal, then he careful what you sign."

## PRESIDENTIAL ADDRESS IN OKLAHOMA

The June number of the Journal of the Oklahoma State Medical Association contains the address of the President of the Oklahoma State Medical Association, delivered May 27, in which Dr. E. S. Ferguson of Oklahoma City discusses the two subjects, the State Health Department and Rural Physicians, as follows:

"Perhaps the deplorable state in which the administration of public health in our own commonwealth finds itself is partially due to the fact that we have kept our light under a bushel. The people of the great state of Oklahoma would not tolerate present conditions if they fully understood the importance of securing a Commissioner of Public Health thoroughly qualified by training and experience to discharge the significant duties of his office and the necessity of perpetuating his tenure until some legitimate cause arises for his removal.

"If properly informed, the people would promptly see the desirability of removing the state health department from the domination of politics and they would act upon this realization. They would make sure that civil service principles governed appointments and removals; that merit and experience would have the right of way over political expediency and the influence of personal friendships. Of greater importance to the citizenship of the state would be the protection of a co-ordinated and well sustained public health program.

"I would suggest that the State Medical Association go on record as favoring a non-partisan health board, the members to be chosen because of their knowledge of public health matters and their interests in the general welfare of the state. The duties of this board should include the selection of a well qualified Com-

A well known Urological Journal says:

Dept. C 680 Fifth Avenue New York City missioner of Health. It should serve as an advisory committee in the administration of the health department and in the appointment of county health officers.

"What a different attitude the public might take could it be brought to realize that medical science has so depleted the ranks of disease in rural communities and so improved and refined the methods of diagnosis that it is often impossible for a physician to retain his self respect, secure legitimate opportunities for professional advancement and at the same time make a living in such communities. The physicians are not, as is often thought, too good in their opinion for the rural community; but the rural community, from the medical standpoint, is not good enough for the physician. What is the solution?

"We must, with the co-operation of the public health, through education, bring the facilities for refined methods of diagnosis and special therapeutic procedures, to the rural communities. other words, we must establish county or district medical centers with well-equipped hospitals as Such hospitals their units. might be partially supported by taxation and partially by private fees. With such a center availthe well-trained young able. physicián can afford to locate in rural communities.

"Once more the need of education is made evident. Let us strive to win the approbation of the public (1) by a continuation of the gracious and kindly practice of the art of medicine; (2) by the judicious pursuit of the science of medicine; and (3) by a modest but confident dissemination of the knowledge which has to do with both the art and science of our great profession."

## For Alcoholism and Drug Addiction

Provides a definite elimination treatment which obliterates craving for alcohol and drugs, including the various groups of hypnotics and sedatives.

Physicians are invited to be in attendance on their patients. Complete bedside histories are kept.

Department of physical therapy and well equipped gymnasium. Located directly across from Central Park in one of New York's best residential sections.

Any physician having an addict problem is invited to write for "Hospital Treatment for Alcohol and Drug Addiction"

# An invaluable diagnostic aid in daily practice

NCE you have learned the advantage and the convenience of having a fluoroscope in your office, you will wonder how you ever got along without it.

You will find it invaluable in making and confirming diagnoses, in determining fractures, in locating foreign bodies and in cardiac, chest and gastro-intestinal examinations.

The Wappler Fluoroscopic Unit is widely used by physicians and roentgenologists. It is of superior construction, simple and convenient in operation and provides ample protection for the operator.

It consists of the Wappler Vertical Fluoroscope, with the Wappler Radiographic

and Fluoroscopic Transformer and Control Unit. The transformer is conveniently placed in the base of the fluoroscope, forming a very compact self-contained unit.

The investment required is surprisingly small for an apparatus of such high quality. Mail the coupon for full information.

KALAK WATER presents a saturated solution of calcium as the bicarbonate.

"Of the inorganic salts of calcium, the bicarbonate was the most effective in raising the blood calcium." (W. H. Jansen—Deut. Arch. f. klin Med. Oct. 1924.)

It is not possible to present calcium bicarbonate as a dry powder or as an effervescent mixture to be added to water. This salt can be maintained as the bicarbonate only in an aqueous solution that is charged with carbon dioxide.

KALAK WATER CO. 6 Church St. » New York City

## WHEN A DIABETIC SAYS:

"What can I eat that tastes good?"

One of the problems in diabetes is to keep the patient diet-happy' And Knox Sparkling Gelatine can be of real service.

As you will note in the recipe below, Knox Gelatine combines perfectly with the foods prescribed for the diabetic diet. It makes dishes that are appetizing and different to the eye and the taste. It supplies the diet variety that satisfies the patient's appetite and it supplies the food-bulk that the patient's hunger craves.

People suffering from diabetes really enjoy gelatine dishes—and they can enjoy them if they have our diabetic recipes prepared by one of the country's recognized dictitians. Remember, Knox Gelatine is free from sugar.

# KNOX is the real GELATINE

# A Serviceable Sedative Adult and Child

IN the milder manifestations of nervous irritability, Luminal in small doses has proved highly efficient. ... The conditions in which it is being widely prescribed for children and adults include the following:

CHOREA

NEURASTHENIA

CARDIAC NEUROSES

MENOPAUSE DISORDERS

**PERTUSSIS** 

DYSMENORRHEA

GASTRIC NEUROSES

HYPERTHYROIDISM

PRE- AND POSTOPERATIVE CASES

A most agreeable form of administering this sedative and antispasmodic is Elixir of Luminal, containing 1/4 grain to the teaspoonful. Its taste appeals to the most fastidious patient.

# Elixir of LUMINAL

"Luminal Trademark Reg U S Par Off and Canada Brand of PHENOBARBITAL

Dose: For adults, 1 to 2 teaspoonfuls, two or three times daily. For children, proportionately less.... To prevent precipitation of Luminal from its solution, it is not advisable to add other drugs to the Elixir.

How Supplied: Elixir of Luminal is supplied in 4 ounce and 12 ounce bottles.

Sample and literature on request.

# HAY FEVER

# An Advertising Statement

TAY FEVER, as it occurs throughout the United States, is actually perennial rather than seasonal, in character.

Because in the Southwest—Bermuda grass, for instance, continues to flower until December when the mountain cedar, of many victims, starts to shed its pollen in Northern Texas and so continues into February. At that time, elsewhere in the South, the oak, birch, pecan, hickory and other trees begin to contribute their respective quotas of atmospheric pollen.

But, nevertheless, hay fever in the Northern States at least, is in fact seasonal in character and of three types, viz.:

TREE HAY FEVER—March, April and May GRASS HAY FEVER—May, June and July WEED HAY FEVER — August to Frost

And this last, the late summer type, is usually the most serious and difficult to treat as partly due to the greater diversity of late summer pollens as regionally dispersed.

With the above before us, as to the several types of regional and seasonal hay fever, it is important to emphasize that Arlco-Pollen Extracts for diagnosis and treatment cover adequately and accurately all sections and all seasons—North, East, South and West.

FOR DIAGNOSIS each pollen is supplied in individual extract only. FOR TREATMENT each pollen is supplied in individual treatment set.

ALSO FOR TREATMENT we have a few logically conceived and scientifically justified mixtures of biologically related and simultaneously pollinating plants. Hence, in these mixtures the several pollens are mutually helpful in building the desired group tolerance.

#### THE TREATMENT OF POLYPOID SINUSITIS\* By G. ALLEN ROBINSON, M.D., NEW YORK, N. Y.

OLYPOID sinusitis, or degeneration of the mucosa of the nose and accessory sinuses is a pathological process frequently encountered and stubborn to treat. The results of medical treatment and surgical measures are usually discouraging to both the patient and the physician. The etiology of this condition is not well understood. It is usually but not always associated with a suppurative sinusitis. Skillern states that repeated attacks of coryza, each one leaving greater changes in the mucosa, contribute to the ultimate forma-tion of polypoid tissue. Influenza appears to be a predisposing factor. Vasomotor changes also play a part in the process, hyperemia of the tissues with a continued exudation of serum into the interstitial spaces plus the force of gravity tends to produce mucous polyps. The pathological picture shows round-cell and leucocytic infiltration in the mucosa, edema of the connective tissue, hypertrophy of the mucous glands, thickening of the periosteum and finally bone absorption. The polyps may appear as myxomatous, adenomyxomatous and angio-fibro-myxomatous varieties. In rare instances a myxomatous polyp may undergo a malignant transformation. I refer to a case in a woman, aged 57 years who had a large myxomatous polyp which filled the right nasal cavity and extended into the pharynx. A suppurative sinusitis preceded this condition. The polyp was removed and both clinically and microscopically was the myxomatous variety. Five months later a recurrent deep purplish vascular mass was noted. The pathological report showed cavernous hemangioma. There was a rapid recurrence and section of the tissue one month later showed an angio-fibro-

The symptoms of polypoid sinusitis depend upon the extent and severity of the disease. Nasal obstruction, mucoid or muco-purulent

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y., June 6, 1929.

discharge, headaches, loss of smell, bronchitis and not infrequently asthma are the chief symptoms.

In the early stages of the disease with a few polyps present, conservative removal, including a small area of surrounding tissue may suffice. In the advanced stages the ethmoid capsule and other accessory sinuses show polypoid degeneration. Hence more radical procedures are undertaken. The late Doctor Sluder has stated that regardless of the surgery-conservative or radical-the end result is that the patient still has polyps. Removal of the polyps does not affect the underlying inflammatory process which must be attacked.

Radium and other physical agents have been used post-operatively in polypoid sinusitis with considerable benefit. The action of radium upon this psuedo tumor tissue is to produce a fibrosis in the sub-mucosa. It is noted that after radium treatments fewer polyps recur and that they are decidedly more fibrous in character than the usual myxomatous variety. The interval between recurrences is lengthened and the nasal discharge diminished. An ethmoidectomy with removal of the polyps should precede the application of the radium. In this way the base of the polypoid areas may be made accessible for treatment. The radiation treatment consists in the application to the ethnioid area one week after radical operation of a 50 milligram radium capsule screened with 0.2 mm. platinum and 1.0 mm. of brass. Only gamma radiations are thus employed. Radon may be used in a similar manner as radium. The time of application is from three to four hours giving 150 to 200 milligram hours per treatment. The applications are made at intervals of ten days to two weeks for an average of four treatments. In recurrent cases after ethmoidectomy the local recurrences may be removed and radium applied immediately. A double string of silk or dental floss is attached to a small ring in one end of the radium

capsule. Vaseline gauze packing is used to maintain the tube in position and is applied between the tube and septum to prevent overaction of the radium on the septal mucosa. The loose end of the string is strapped securely to the patient's cheek and around the ear as there is a possibility of the tube being dislodged to the nasopharynx and swallowed.

In a small group of cases usually in young people in which there are large vascular polyps, gold radon implants of 1.0 millicurie each may be inserted into the tumor tissue using one implant to each cubic centimeter of tumor tissue. Hemorrhage is thus controlled and operation is performed four to six weeks later. This type of treatment also applies to another pathological process, the fibromas of the nasopharynx, many of which will disappear after radium treatment or reduced in size and made avascular and rendered safely operable.

In polypoid disease of the maxillary antrum radical operation, preferably the Caldwell-luc is performed. Recurrences do not appear to be as frequent as in polypoid ethmoiditis. An intranasal opening into the antrum should be maintained so that endoscopic examinations may be made. It is more difficult to apply radium in the antrum than the ethmoid area. However, small radium capsules may be inserted into the antrum through the intranasal opening, or radon implants of not more than one millicurie strength may be inserted into the recurrent polypoid mucosa. A recent case referred by Dr. William Holden, a woman 56 years of age, gave the history of asthmatic attacks for many years with nasal catarrh and finally impaired hearing. Her asthmatic condition had been treated for many months by vaccines without improvement. Dr. Holden performed a bilateral Caldwell-luc operation and many large polypoid masses were removed. The asthma disappeared and patient remained well for a year, when the attacks recurred. Endoscopic examination at this time revealed four of five polyps three to eight millimeters in diameter in the right antrum.

The left antrum was free and the ethmoid areas showed thickened mucosa but no polyps. Five 1.0 millicurie gold implants were inserted into the polypoid masses in the antrum and after a few days the asthmatic attacks disappeared. The ethmoid areas have received treatment by means of the radium capsule.

The patient's condition is markedly improved, polypoid areas in anthra have become fibrous and a shrinkage of the hyperplastic mucosa in ethmoid area has been noted.

#### SUMMARY

1—In a series of forty cases of polypoid sinusitis treated by radium twenty-eight had

previously received surgical intervention by partial or complete ethmoidectomy and antrotomy.

- 2—Asthma, a complicating factor in nine cases, was controlled in seven.
- 3—The mucoid and muco-purulent secretions have been lessened.
- 4—Headaches have been relieved and in a few cases the sense of smell has returned.
- 5—Small polypi have been made to disappear and the interval between the recurrences has been lengthened.

#### Discussion

John J. Rainey, M. D., Troy, N. Y.—! became interested in the treatment of polypoid sinusitis with Radium several years ago About that time the late Doctor Sluder of St Louis published a paper in the Laryngoscope giving his experience with Radium in this disease. Later he discovered the paper written by Lyons and acknowledged him as the pioneer. (It was the experience of Lyons nine of ten years ago that encouraged me to use Radium. My results have been uniformly good.) To one class of patients in particular, Radium is a blessing. I refer to those who have had as many operations for polypi as there are specialists within a radius of fifty miles.

I should like to quote one case: Female; age, 50 years in 1926; complained of constant cold in the head, difficulty in breathing, frequent attacks of asthma. She had several operations for removal of nasal polypi, followed by a stay in California with no benefit. The polypi were small and confined to the ethmoid region. These were removed in October 1926. Beginning 10 days later she was given 150 mg. hours every twelve days for three treatments. The swollen ethmoid region still persisted. In December of the same year she was given 200 mg. hours for three periods at twelve day intervals.

For a month after she had no perceptible benefit. She then spent nine months in California and came home relieved of all her symptoms and is enjoying splendid health. I suggest that radium be used in frontal sinus operation instead of the radical Killian. Care should be used that the capsule does not slip into the pharynx and swallowed.

Tissues should be sent to the laboratory for complete examination.

Since Lyons' original paper there have been several on this subject. With the exception of one or two none in my opinion could add anything to his. I feel, however, in Dr. Robinson's paper we have one that is refreshingly brief, authoritative and the last word in the treatment of polypoid sinusitis.

#### WHAT IS AHEAD IN MEDICINE

By WILLIAM H. ROSS, M.D., BRENTWOOD, N. Y.

An address by the President of the Medical Society of the State of New York before the Women's Medical Society of the State of New York at its twenty-fourth Annual Meeting on Monday, June 2, 1930, in the Hotel Seneca. Rochester, N. Y.

OT long ago there was an editorial in the New York Herald Tribune on "Evolution and Health." And one paragraph said:

"Much of the present muddled state of affairs in the medical profession as to its relationship is due to the transition of a changed front of mankind toward disease. Physicians are increasingly the conservers and suppliers of the positive commodity of good health; decreasingly the emergency repair men called in only when something has gone wrong. No one can doubt that the change is for the better, although the transition is not, nor can be, alogether painless."

is not, nor can be, alogether painless."

Is the medical profession living enough in the

present or is it adhering too much to traditionthat subtle influence that so often controls us and is defined well by Dr. Wilber as "that process by which one generation seeks to secure its conclusions from change by the next generation." When Emerson tells us that "we inherit the follies and stupidities of mankind as well as its progress,' it should make us think of the dangers of living too much in the past and being guided too much by its influence and not coming into professional relationship to the new things in better health. The medical profession must create a new relationship and establish a new adjustment to correspond to present day social trends because these social trends are leading to new public demands. If we do not do these things, there is danger of a declining influence in the years to come. There was once a time when every man was in control of his own relationship to others, but in these days groups of people work together and individual relationships no longer can be depended upon as a professional guide.

There is a great deal of talk of the preventive era in medicine, but it is just because we have rather suddenly recognized a new condition. The factors that have produced this so called new era have been going on a long time. We have not thought of them as an evolution. Prevention was applied to scurvy one hundred fifty years ago; to smallpox one hundred thirty-two years ago, and to many other diseases as bacteriology developed during the last fifty years. But this does not answer the problem, because the new attitude of mankind toward disease and the public knowledge of medicine create a new situation that can only be met by a new relationship. If the public were not advancing about as fast as we are in the effort to improve health, we would not have to consider questions of relationship so quickly.

Medicine has come to have a public character because the public has become educated in health matters. Government has become more interested in health and in welfare. The semi-governmental effort in the White House Conference to build child health into civilization, and the effort to find the facts regarding the high cost of medical service headed by the Secretary of the Interior,

are striking examples.

There is another fact confronting the medical profession, a natural economic trend downward unless we readjust our relationship to the new demands and new conditions. The greatest objective of organized medicine is the improvement of its science and art; and just as this advances, disease diminishes and there is less work to do unless new work is taken on. Just now there is a readjustment going on not entirely unlike that which comes from a disturbance of the law of supply and demand in production or in industry. Preventive work must be more largely incorporated with medical practice in order to restore the balance. However, the more one studies these things, the less serious economically they seem to be. It seems as if they would almost cure themselves if we just keep along with present tendencies in a spirit of cooperative relationship.

Even though there are many health activities going on technically outside of medicine, there is just as much need of physicians as there ever was. It simply is a little less along curative lines and a little more along preventive lines. These two can keep a balance; and that is all there is of it. It is sheer absurdity to get excited at all about these conditions. The remedy for it all is to go along with present day social trends and with the results produced by the welfare activity of governments and official agencies and with the interests of the general public in more health, along lines of cooperation, and become the medical part of all this present great irresistible movement; and when that is done, have confidence in This is just as important for the profession as it would be in Wall Street.

I read a paper on a subject closely related to this at the New York County Medical Society last year. Afterwards I heard a very interesting discussion. I came to the conclusion that all the resolutions in the world would not stop pay clinics, group practice, life extension and medical centers; but that open-minded association of practitioners of medicine with them (in a cooperative relationship), would give an opportunity to minimize the evil and capitalize the goodand the good outweighs the evil. The profession is standing in its own light if it continues to oppose these movements that are simply the result of the social trends of the times. Evolution is steadily going on in everything else in the world

—in industry, in business, in civic affairs, and in government—and medical practice and public health are no exceptions.

One of the most ticklish questions is the interrelationship of the medical profession and the health organizations. A relationship exists and has always existed, but it has not usually been realized until some group has objected to the activity of some other group. This relationship, unrecognized until something happened, until somebody believed that their rights and privileges were interfered with, has so often created a disturbance that was inimical to the advancement of public health that it has led to the formation of a Standing Committee of the Medical Society of this State known as the Public Relations Committee. The primary duty of this committee was to undertake the harmonizing of differences between the medical profession and health organi-From that starting point the Public Relations Committee has gone forward into a statesmanlike conception of the purposes of organized medicine and the need for readjusting its relationship to other agencies in line with the natural forces of society and the present day social trends that have caused medicine to have its public character and have caused the public to make certain demands in health service that did not exist even ten years ago.

The Public Relations Committee is an outstanding committee of the Society in its capacity to influence public opinion and to help to reestablish the influence of the family physician in human affairs. This committee appeals more largely to the common sense of laymen and to the ideals of medicine. It appeals more largely to the character, integrity, and honor of the profession; and as time goes on it must stimulate more and more correct medical organization and stress the two great purposes for which organized medicine exists, namely, the advancement of the science of medicine and the betterment of public health.

Contact with many medical men this year in many medical meetings makes me believe that the medical profession should adopt as a principle a cooperative relationship with every health or welfare effort in the State, and that it should not wait for an invitation. The profession should go to the State government or any of its departments with an offer to help in any public health project. It should go with a plan for betterment, and in the spirit of conference, and with the objective of the advancement of public health, public welfare, and the common good.

The profession ought to follow the same plan with the unofficial health agencies, child welfare organization, and parent-teacher associations. In no other way will we ever secure the leadership that we ought to have, and avoid the danger of a declining influence.

Previous to three years ago there did not exist an organized effort on part of the medical profession to cooperate with other health agencies. There was not a definite organized effort within the profession for the betterment of public health and the welfare of the practice of medicine by cooperation. Both of these objectives are now coming to be considered essential and we are, therefore, making progress.

The leaders of the profession have generally sensed the danger of continued indifference to health effort of unofficial health agencies. contacts with medical men increase in number, there comes the sense of an awakening to the influence of present day public opinion in regard to health and the danger of professional disregard of an effort to unite all the forces, working in the interest of better health. The public shows many evidences of its believing that protection from disease is essential to the economic and social welfare of people; and there are many evidences that the profession is beginning to realize that cooperation with health agencies is essential to its economic welfare also. If these observations are correct, then it is only a matter of time until the whole profession will come to see the view point that the leaders of the profession have seen and that men of vision in the profession now recognize.

There is a common ground for agreement, and the Public Relations Committee is endeavoring to set up a program based on the cardinal principle of cooperation that will benefit the public as well as the profession, and that will grow as the years come and go until the profession of medicine is again the mighty force, through the family physician, that it once was in human affairs.

The work of this committee is creating medical and public interest which is the first essential in the building up of any program that is to be of value to the public and to the profession also.

Up to about three years ago there was a great deal of misunderstanding, suspicion, distrust of health agencies, and of any welfare health legislation. That there is an evolution going on in the attitude of the profession is shown by the fact that there is much less misunderstanding, suspicion, distrust of health agencies, and of welfare legislation. Today there is considerable unity and cooperation between health and welfare agencies and the medical profession.

So long as unselfish men will lead the effort to establish cooperative relations with all health and welfare agencies having the same ideals as medicine, and will meet them in a spirit of conference with a program that these agencies can join in with and then ask them to advance it by a program of education, there will slowly be laid a secure foundation that will mean a better profession, rendering greater public service.

This talk and these comments on Public Relations applied to medicine and my experience in working with this Committee for three years express something of the expectation and outline, in part, the plan that I hope to advance next year.

In conclusion I want to add that what Edward Bok did for American commerce in advocating advertising, should let us see the power of advocating that the profession of medicine assumes the proper relationship to health organizations and to the public health generally. We should not try to reform other factors in the great health movement today until our own attitude is re-

formed into a spirit of cooperation. As an inspiration we might adopt Bok's creed:

"Wherever your lives may be, make you the world a bit more beautiful, and better, because

you have lived in it."

There is more than medicine in a doctor's life. It is something greater than that. Often a doctor comes nearer to awakening finer things in an individual than anyone else does in human relationships. Beyond what we know and beyond what we do, there may be an influence that we do not realize. A doctor sees things face to face. There is a something and no one knows what it is because it is not measurable.

### BILATERAL TUMORS OF THE TESTICLE. REPORT OF TWO CASES\* By J. L. WOLLHEIM, M.D., NEW YORK, N. Y.

TUMORS of the testicle are not particularly common. They occur as one half of one percent (½ of 1%) of all tumors or one in two hundred. They are quite rare over the age of fifty. Bilateral growths of the testicle are of very great rarity. A very thorough search of the literature made by Hinman', revealed only seventeen cases of bilateral testicular tumor reported. Higgins', of the Cleveland Clinic reported one other case. Several other cases were reported but their authenticity does not seem clear. My two cases here reported bring the literature to twenty. Archie L. Dean's of the Memorial Hospital, N. Y., saw or has records of one hundred and sixty-five cases of tumor of the testes and never came across a bilateral case.

In order to more thoroughly understand the subject of the rarity of bilateral testicular growths, a brief resumé of the new pathology should be undertaken. The most recent classification varies tremendously from that of old. Ewing, Chevassu, Hinman, Schultz, Eisendrath', and others have done an immense amount of work on the pathology of these growths, and I believe that the classification as given by Young', is the most practical of all.

All tumors of the testicle are supposed to be malignant with but a very small percentage of benign ones, and even these according to some authorities are malignant, if only the specimen is gone over more thoroughly. Pathologically they are divided into three classes according to the number of embryonic layers contained in them.

1st class: Seminoma, a type of malignant tumor probably springing from the seminifer-

\*Presented in abstract form before the Yorkville Medical Society, New York, on May 20, 1929.

ous tubules. It contains only one type of cell and is decidedly malignant. Ewing claims that though usually only one type tissue can and is seen, that a thorough study of them reveals them as multiple layer tumors embryonically.

2nd class: Teratoma or Embryoma, a type of malignant tumor having several types of tissue, and springing from two or more of the original embryonic layers. Though one type cell may predominate, it probably shows the evergrowth of that type cell, among other types of cell. They always show evidence of having sprung from two or more layers. Teratoma and Seminoma make up probably over 95% of all tumors of the testes.

3rd class: An occasional tumor of the testicle showing tissue not like the above two classes, and in them we can recognize pure fibroma, adenoma, endothelioma, sarcoma, pure myoma, and a tumor like case one here reported, lympho-sarcoma exceedingly rare.

Tumors of the testicle never infiltrate or involve the tunica albuginea though they infiltrate the testicular structure, and finally replace all of it in the malignant cases. In the benign cases the tumor is often found pushing aside the testicular tissue aside but never replacing it. Incidentally it is interesting to note that primary tumors of the epididymis are never seen. Malignant tumors of the testicle may be accompanied by secondary hydrocele and the tap is usually bloody. The glands draining the testicles are rarely felt, as they are not inguinal but iliac, aortic, retro-renal and thoracic, and this fact has a bearing on treatment.

After these few preliminary remarks two unusual and interesting cases of bilateral primary tumors of the testicles are here reported. Case No. 1: Bilateral primary lympho-sar-coma of the testes.

Chas. T., referred to me January 20, 1926. Age 66: Married: Hotel proprietor, had a history of chancre forty years previously, present illness, painful swelling right side scrotum for six weeks. Examination showed a nodular swelling of both the right and left testes, epididymes and vasa. All markedly infiltrated. There was also a secondary hydrocele on the right side. Prostate and vesicles felt normal, there was no discharge from the urethra, and the urine was clear. There were no glands felt and the remainder of examination was negative. Blood Wasserman was negative. Hydrocele showed bloody serum, it looked clearly like a primary tuberculosis and available to surgical removal. January 26, 1926, I removed both testicles, epididymes, and vasa up to the internal rings and there the vasa seemed quite normal. Pathological report: "The specimen consists of two testes, (right and left) each testis possessing an attached and intact epididymis. Both testes appear larger than the average in size, measuring about 5cm. in the diameter by 3.5cm. wide and 2.5cm. in thickness. testis is structurally normal and covered with a smooth, uniform, glistering fibrous capsule. Both epididymes are increased in diameter thruout the entire length, the increase being most marked in the testicular segment. The glistening tissue which appears uniform thruout their course. On section both testes appear essentially alike and reveal a uniform, light, cream colored, firm, and somewhat soft, nearly homogeneous tissue. This tissue extends to the tunica albuginea. No normal appearing testicular tubular tissue can be recognized. The epididymis on section present somewhat similar, cream-colored tissue with considerable admixture of epididymal and connective tissue."

Microscopically, "multiple sections representing all parts of both testes and epididymes present, extensive atypical cellular tissue, in many areas completely replacing the original tubular tissue, of the testes. In other areas there is an occasional tubule which appears embedded in the surrounding infiltrating cellular tissue mentioned above. The cells of this tissue are mononuclear, they are slightly larger than the normal monocyte. They possess a moderately large nucleus with a definite zone of cytoplasm. All of the cells stain deeply, the cytoplasm especially appearing basophilic. These cells show a remarkable uniformity in size, shape and staining properties. There is a considerable proportion of mitotic cells scattered thruout the above cellular tissue.

Thruout this cellular tissue is present a moderate degree of fine, fibrillar, reticular fibrosis. Microscopic sections of the epididymes show structurally intact tubules. There is a varying degree of atypical cell infiltration of the areolar connective tissue, these cells resembling closely those described above. The cellular infiltration is most marked in the lower pole being essentially diffuse in extent. In the upper poles and in the cords proper the atypical cell infiltration is more focal in extent, many of the foci being perivascular. The above description would appear to include all of the pos-The above desible pathological changes present. The condition is characterized by an extensive diffuse infiltration and replacement of both testes and epididymes by an atypical, mononuclear, hyperchromatic, and hypermitotic cellular tissue resembling most closely in its structure that of normal lymphocytic tissue. The pathologic diagnosis is: Bilateral lymplio-sarcoma involving both testes nd epididymes. Pathologic Discussion:—The above pathologic findings would indicate a simultaneous involvement of both testes by a clinically primary lympho-sarcomatous process. The possibility of this condition representing an extension of a pre-existing abdominal lympho-sarcoma should be considered."

Signed: W. E. Youland. M.D.

most marked in the testicular segment. The epididymes are covered with a smooth fibrous glistening tissue which appears uniform thruout their course. On section both testes appear could be felt.

Why primary? Because at the time of operation no other lesions could be noted, the procular state and entire pelvis felt normal, no glands could be felt.

Young reports an unilateral lympho-sarcoma, and Kocher describes a "lymphoid" sarcoma and notes that it is very malignant.

This patient died of generalized abdominal masses, within six months after operation.

Case No. 2: Bilateral primary tumor of the testicle.

The second side involved with malignant teratoma, twenty-seven years after the removal of the first testicle for tumor. Mr. A. P. T., age 54: referred to me January 16, 1929, with large painful swelling left side of scrotum of about one year's duration. Previous history (this is of much interest because it may show some relation of trauma to tumor growths). In 1898 while in the Spanish War, patient fell astride a fence with an eighty-pound pack. He crushed both testicles but in time the swellings subsided. Two years later, however, (1900) the right testicle began to swell and continued so till (1902) when a very large tumor was removed with the testicle. This operation was done at the Lutheran Hospital in St. Louis and the size of the tumor was said to be tremendous. The exact report could not be obtained as the records were destroyed by fire

in 1916, and as the hospital never made routine microscopic examinations, the exact type of tumor could not be ascertained. To quote a recent letter from the Lutheran Hospital. "In those days we did not make any pathological or microscopic reports. All our records were destroyed by fire in 1916" (what a pity).

After this operation the remaining testicle seemed to atrophy for awhile but later it developed again. The patient married later and

his wife bacame pregnant four times.

The present illness began about one year ago or twenty-seven years after the removal of the first testicle. The left testicle got larger and harder till operated on by the author, April 13, 1929. There were no glands felt anywhere and the Wassermann reaction was negative. Before operation patient received four preventative x-ray exposures to scrotum, abdomen, retro-renal region. Operation was under general anesthesia, and no post operative complications developed. After operation he was given ten more deep x-ray exposures. Tumor weighed 242 grams, (8 oz.) but very much smaller than the other side according to patient.

Pathological report: Gross examination shows a well encapsulated tumor with extensive necrosis. Weight 242 grams. Histological examination shows as embryonal carcinoma of the testicle which we consider prob-

ably of the teratomatous origin.

Signed: Elise S. L. 'Esperance.

That the first tumor was a tumor we need hardly doubt, as the patient is a dentist who is versed in pathology and is definitely positive it was many times the size of present tumor

and was told it was a large fibroma. Personally I doubt the fibroma, as all sarcomata (old classification) are stony hard and feel like fibromata. I believe it probably was a well encapsulated (within the tunica albuginea) teratoma, as most of these tumors are. At any rate it was a tumor and that is what interests us only now.

At present time patient is doing exceedingly well, gaining weight, but we can't tell the outcome for some time.

A word about the pre-operative, operative, and post-operative precautions. These cases should be deeply x-rayed to scrotum, pelvis, retro-renal region before operation. At operation the cord and vessels should be tied off before the tumor is manipulated, the vas stump as precaution should be cauterized and the entire operative field and cavity should be treated with alcohol to be sure of no transplantation of tumor cells.

Post-operatively these cases should be exposed at least several times to x-ray to destroy any possible pelvic, iliac, aortic, and retrorenal glands, the last should be done posteriorly.

# TURNING OVER A NEW LEAF

The meeting of the House of Delegates marks the end of a formal year of the Medical Society of the State of New York, and the beginning of a new administration. Yet there is no break in the activities of the Society, or confusion in the change of officers, for there is a continuity of both the essential personnel and the policies of the Society. This Journal has frequently carried

attention to the continued activities of the presidents and the chairmen of committees after their terms of office have expired. Office holding in the Medical Society of the State of New York is a school which inspires the officers to continue their leadership. The new officers simply turn over a new leaf of the unified records of the Society.

## PRESIDENT'S COMMENTS ON CURRENT ACTIVITIES

The Special Commission, appointed by the Governor to study the adequacy of the present health laws and the need for a revision of the health program of 1913, has had one meeting. Fourteen subjects were assigned for study,

one to each of the members, with authority to appoint others to assist in the study from within or without the commission.

The following are the subjects to be studied and the chairmen of the committees to whom they are assigned:

1. Medical Care, Dr. Ross.

2. Cancer Control, Dr. Cottis.

Social Hygiene, Dr. Keyes. 3.

- Industrial Hygiene, Mr. O'Hanlon. Health Education, Mrs. Leach.
- 5.
- 6. Mental Hygiene, Mr. Folks.
- 7. Health Laws and Sanitation, Dr. Nicoll.
- State Aid. Dr. Parran. 8.
- 9. Tuberculosis, Mr. Kingsbury.
- 10. Public Health Nursing, Miss Tucker.
- 11. Laboratories, Dr. Simon Flexner.
- 12. Maternal and Infant Welfare, Dr. Farrand.
- 13. Orthopedics, Mr. Morganthau. 14. Public Health Personnel Training, Dr. Linsly
- R. Williams.

From time to time there will be reported the

progress of these committees.

The Executive Committees of most of the District Branches have met in the last month and selected the places and dates for their next annual meetings. At the same time, in conference with the Presidents of the component County Societies, they have outlined their tentative programs.

Physicians have been showing an increased interest in the affairs of the District Branch in most sections of the state. According to registration records, in the last two years the total attendance at the annual meetings of the District Branches has been greater than at the annual meetings of the State Society, and it is surprising to know that only a small number of the men who attend the annual meeting are registered also at their District Branch meeting.

In preparing the programs this year, the committees are uniformly providing a place for the discussion of subjects relating to the economics of the practice of medicine, including a discussion of the physicians' part in the administration of the new Public Welfare Law and in the administration of the Workmen's Compensation Law.

As physicians, we are being called upon much more frequently than in the past to help communities solve their medical problems and, therefore, it is important that our programs should not be limited to subjects relating to our scien-

tific advancement alone.

Dr. Allen Freeman, Professor of Public Health Administration in the School of Hygiene at Johns Hopkins University, who last year made a public health survey of Steuben and Suffolk Counties, recently submitted a typewritten copy of his survey to the Steuben County Medical Society. The report is very elaborate, extending over more than two hundred typewritten pages A few exceptions were taken to the report as presented; these were discussed and Dr. Freeman will make revisions in accordance with the suggestions for the final draft of the report

It is understood that other surveys are to be made and the reports finally published in book

form.

About two weeks ago Dr. Freeman began a similar survey of Ontario County. We are hoping that the physicians will aid him in this survey. Here is an opportunity for the physicians who are not health officers to have record made of the public health work they do in connection with their private practice. It is well known that the health officer is greatly aided by the general practitioner, but never before has an effort been made at its evaluation.

The County Society of each county under survey should invite Dr. Freeman to a regular meeting, or to a special meeting if that is more convenient, for the purpose of meeting him before he begins his survey, in order that he may be able to explain what he particularly desires to incorporate in his survey. His findings, when finally published, are likely to be considered an authority not only of the public health activities of the county, but of the full medical activities as well.

W. H. Ross, President.

# THE HOUSE OF DELEGATES

This issue of the Journal, pages 777-795, contains the minutes of the annual meeting of the House of Delegates of the Medical Society of the State of New York, which took place on June second and third. To record exactly what takes place requires time and labor in both the secretarial and the editorial offices. Not only must the actions be recorded, but the record must also contain cross references to other resolutions and even to the proceedings of previous years. The fact that the minutes, filling nineteen pages of the Journal, were prepared in time for the July first issue is a demonstration of the efficiency of the secretary's office.

The minutes cover an unusually comprehensive range of subjects, nearly 100 sections being required, as compared with about 60 last year. Yet very few topics of a controversial nature were discussed. A preliminary description of the proceedings of the House of Delegates on page 734 of the June fifteenth Journal said:

"It was a striking fact that every controversial question and every suggestion for extending the field of the activities of the State Society had been under discussion during the year, and that some committee was prepared to give a definite opinion on the subject. The discussions revealed an unexpected breadth of the investigations, and a comprehensiveness of decision on the part of the officers and committeemen. The proceedings were convincing evidence of the great extent which the intelligent evolution of State Society activities has undergone during the last decade."

This opinion is confirmed by the close study required by the preparation of the minutes.

The peculiar work of the editor has been that of paragraphing and indexing the minutes. The editor is credited with an eagle eye and a mind that is literal and unimaginative. If he understands the minutes, it is reasonable to suppose that they are intelligible to the readers of the Journal.

# LOOKING BACKWARD

# This Journal Twenty-Five Years Ago

Venereal Disease Education: A quarter century ago popular education regarding venereal diseases was only timidly suggested, although the Society for Social and Moral Prophylaxis had been formed. Dr. Edward L. Keyes, Jr., writing in this Journal of July, 1905, said:

"I am not at all sure but that, if every boy in this world were given the best possible chance of avoiding venereal disease, more than half of them might not go ahead and get infected anyhow. But the point is, they don't get the chance.

"We are not giving our children or our fellows a fair share of the enlightenment which we possess, or ought to possess. They have a right to freedom and all means necessary to its attainment; they have a right to virtue and health and all means necessary to their attainment. The practical difficulties in the way of

imparting this necessary knowledge in such a way as to produce a good moral effect are great, but not insuperable.

"The spirit of the Society for Social and Moral Prophylaxis will not die. The rumor must spread; it must interest brother and son as well as mother and wife, prelate, and physician, and father of family. I cannot doubt that, in the end, it will produce a marvelous change in public spirit, that, as it was the triumph of the eighteenth century to make seduction unfashionable and of the nineteenth to make drunkenness unfashionable, so it may be the glory of the twentieth to make the law of public opinion the same for man as for woman."

The prediction has been fulfilled, and Dr. Keyes is still a foremost leader in the movement.

# MEDICAL PROGRESS

Familial Nosebleed Without Hemophilia .--Professor Hans Curschmann reports several cases of very severe nosebleed in two families of Jews (which were unrelated). In the first family the patient was 54, his father, an uncle and an aunt died of nosebleed and two others in the family suffered from the same affection. while six others seemed immune. The patient developed the disease at 25, although in the earlier generation it began around puberty. His attacks, which recurred every few weeks, often threatened life. Aside from this symptom, he showed no hemorrhagic tendency and his brothers and sisters were free in this respect. Nothing abnormal was found in the nose. The spleen was slightly enlarged. The other organs in the body were approximately sound. The red blood cells were somewhat reduced but the blood counts as a whole were normal. The behavior of the thrombocytes and the coagulation time of the blood were normal. The author did not have the opportunity of studying the patient during an attack. The patient of the second family was also aged 54 and a maternal uncle likewise had suffered from recurrent nosebleed. Aside from these two cases there were no bleeders in the family. The patient had suffered since childhood and every few weeks, according to the family physician, "literally swam in blood." He was otherwise normal and even the spleen was not enlarged. Although the nose had been repeatedly cauterized, a rhinologist pronounced it quite normal. The blood counts, coagulation time, etc., were within normal limits. Differences between these two cases and hemophilia are at once apparent, for in the latter females are regarded as immune and it is never restricted to one location in the body. We may for the time being style these cases as familial, monosymptomatic, pseudo-hemophilia. Doubtless many mild abortive cases could be added to this list. Under the head of treatment the author states that local treatment habitually failed, and he does no mention internal hemostatics. The most successful treatment, whether or not the blood is normal, is irradiation of the spleen.-Klinische Wochenschrift, April 12, 1930.

The Mechanism and Treatment of Prostatic Obstruction.—Kenneth M. Walker reviews at length the mechanical and dynamic or spasm theories of prostatic obstruction, which lead him to the conclusion that the most satisfactory explanation of retention is that there exists a constant mechanical obstruction acting

along the lines suggested by Swift Joly and that this is supplemented by the variable factors of congestion and spasm. He takes issue with the tendency in some quarters to regard the fact that the gland is enlarged as the allimportant point, and as a consequence its removal as the primary object of treatment. It is dilatation of the bladder and embarrassment of the kidneys, rather than the enlargement of the prostate, that should preoccupy the medical man who is called upon to care for a patient with prostatic enlargement. Although for a large number of patients total removal of the gland is the best and possibly the only measure available, there are others who neither require, nor should be subjected to, this ordeal. In cases in which there is a marked intravesical projection, total prostatectomy may be the operation of choice, but in some cases a permanent cure may be obtained by removing only the enlarged middle lobe. Since, according to Joly's theory, it is the height of the enclosed portion of the intravesical projection that is the determining factor in causing the obstruction, it is of great importance to remove not only the free portion of the middle lobe that projects into the bladder but also the V-shaped segment at its base. If the projection is a large one, this is best done by open operation; if inconsiderable it may be done with great advantage by a large electrode working through an operating cystoscope. Bar formations are best destroyed by diathermy applied through an operating cystourethroscope, or by means of a diathermy punch, though the fibrous type not infrequently yields to such simple measures as dilatation of the bladder neck by bougies, instillations into the posterior urethra, and prostatic massage. The author finds that an increasing number of cases of prostatic obstruction are becoming amenable to perurethral methods of treatment.-British Medical Journal, May 3, 1930, i, 3617.

The Age and Sex Incidence of Carcinoma.—Theodore R. Waugh and T. L. Fisher present statistics on the age incidence of carcinoma from the records of the Royal Victoria Hospital, covering the period from 1915 to 1928. A total of 22,993 surgical specimens were examined of which 1,756, or 7.63 per cent were primary cancerous growths. Of this 1,118 or 63.6 per cent were from females, and 638, or 36.4 per cent were from males. The average age of all the patients was 53.5 years, that of

the females 50.6 years, that of the males 56.5 years, a difference of approximately six years. Comparing the figures for each year there was nothing to suggest that toward the close of the period cancer tended to occur in younger individuals, or that the public, as a whole, on account of being better informed, sought treatment at an earlier age. In the five year periods the age incidence in all cases, both male and female, shows a gradual increase up to 50 years, a fairly constant number up to the 65th year, and then a rapid decline. While there are fewer cases of cancer in individuals over 60, the probability of having the disease increases for those who live beyond that age. With reference to the involvement of various organs, the breast led by far with 455 cases, or 25 per cent; next in number was the cervix with 231 cases, or 13.1 per cent, and then the lip with 125 cases, or 7.1 per cent. The cervical growths were principally premenopausal; endometrial growths, post-menopausal. Of the 125 cases of cancer of the lip, all but five were in males, a ratio of 24 to 1. There was a steady rise in incidence from the youngest patient, who was 30 years of age, to the 55 pear period, suggesting an ever increasing ratio of incidence to male population as the years go on. There were 51 cases of cancer of the prostate, or 2.9 per cent of the total cases. This in no way represents the true frequency of involvement of this organ, as many patients go unoperated upon and undiagnosed, as any autopsy service will show. A study of the involvement of various organs shows distinctly that carcinomata arising from glandular epithelium tend to occur on an average earlier than those from squamous-celled epithelium, with the exception of the cervix and prostate both of which derive their epithelium from the mesoderm.—Canadian Medical Association Journal, May, 1930, xxii, 5.

Treatment of Pernicious Anemia with Dried Pig's Stomach.—Prof. G. Rosenow. internist at the Hufeland Hospital, Berlin, calls attention to the occasional failure of liver diet in this affection, and also notes the high price of liver and the desirability of other preparations as a reserve. The pioneer in substitutes is Castle of America, who found that predigested muscle fiber with hydrochloric acid had the same value as liver and he assumes that the achylia is a cause rather than a result of per-Other experimenters have nicious anemia. tested powdered dried pig's stomach with the favorable results already known. Dr. Rosenow has thus far treated but two patients with a preparation made according to the American formula, but the results are so brilliant that he feels justified in reporting them. There was steady improvement while the treatment was maintained and no recurrence after the remedy The achylia still continued, was discontinued. however. Characteristic was the marked increase of the reticulocytes during the first days of treatment. The blood picture became normal and the general condition improved in proportion. Severe secondary anemias did not respond to the treatment. Powered pig's stomach has also given good results in Vienna, at the Mayo Foundation, and in Holland and thus far no failures seem to have been noted. In addition to other advantages over liver extract is economy of dose, only about one-third as much being required. It is evident that the new preparation opens up therapeutic possibilities not only in pernicious anemia but in other fields.—Klinische Wochenschrift, April 5,

The Present Status of Pernicious Anemia.— Prof. P. Morawitz states that this common affection is still insufficiently known to general practitioners. The success of the new liver treatment has made it obligatory for them to make correct diagnoses. Although the patients have a peculiar yellowish white color, the nutrition is often excellent. The condition requires careful differentiation from numerous secondary anemias. The patients mostly complain of exhaustion, palpitation and indigestion, which are not typical. Important symptoms pertain to the tongue and nervous system. At least half the patients give a history of the peculiar glossitis. One of the author's patients had the painful tongue for twenty years preceding the disease proper. Almost equally common are abnormal sensations in the tips of the fingers and toes. A much enlarged spleen is evidence against pernicious anemia. The urine is mostly dark, the reverse being found in secondary anemia. The occasional association with disease of the spinal cord is well known. A diagnosis cannot be made from the blood picture alone, for the so called characteristic picture is sometimes found in secondary anemias. The alleged frequency of achylia gastrica which is not overcome by histamin injection is a moot point. After testing 500 cases the author is unable to generalize. In some cases of achylia, cancer of the stomach is present. If hydrochloric acid is present we must revise the diagnosis very carefully. Achylia doubtless indicates atrophy of the stomach from one of various causes. The liver treatment has not been known to influence achylia favorably. This is also true of spinal cord complications. Liver is not exactly a specific for pernicious anemia, for it is often of value in secondary anemias, notably those due to hemorrhage. Raw liver is the most active form, as strong heating damages the active principle. Marked increase in hemoglobin is a

signal for reducing the dose of liver. Rectal feeding with liver is said to be of value but the author has not yet tested it. Dried pig's stomach is recommended, but the author suggests fresh preparations as being more efficacious. The new forms of treatment can hardly be called curative but they have done much toward prolonging life and relieving symptoms. In other words they are on a par with insulin in the treatment of diabetes.—Münchener medizinische Wochenschrift, April 4. 1930.

Muscle Extract in the Treatment of Angina Pectoris and Intermittent Claudication.—Lcd by the report of J. S. Schwartzman of Odessa on the treatment by muscle extract of angina pectoris, particularly of the variety known as "angine d'effort" or angina ambulatoria, M. S. Schwartzman has employed this method with very promising results. The underlying considerations on which the administration of muscle extract is based are was follows: J. S. Schwartzman, in 1927, described a peculiar phenomenon which occurs invariably with a hypotonic heart muscle, as in infectious diseases, anemia, cachexia, chronic pulmonary tuberculosis, heart failure, etc. If the patient contracts any muscle group, there are noted a muffling of the heart sounds, shortening of the systole, diminution of intensity, or even disappearance, of systolic murmurs, if any have been present; all this being the result of a diminution of the amplitude of the cardiac contraction. This heart reflex bears a certain resemblance to what happens in angina pectoris, in which the coronary angiospasm might be accompanied by muscular spasm. It has been observed that a few preliminary exercises would abolish the phenomenon, and the fact is known that anginal pain sometimes disappears if the patient continues his effort. Hence arises the assumption that some antispastic substance is at work during the contraction of active skeletal muscle, and that such substances obtained from the skeletal muscle of a healthy young animal might counteract the spasm in angina pectoris. Their deficiency in the muscular system, on the other hand, would be an important factor in the production of the anginal syndrome. The author reports an illustrative case of angina ambulatoria treated by daily injections of muscle extract for three weeks. After the third injection there was an improvement in sleep; after the sixth injection the sensation of constriction about the chest diminished, and after the twelfth injection the patient was able to walk two and a half miles without discomfort. In view of the striking resemblance of angina pectoris to intermittent claudication, the treatment was applied to cases of the latter condition with encouraging results.—British Medical Journal, May 10, 1930, i, 3618.

Acetylcholine in Arterial Embolism .- G. Faroy and H. Desoille state that this substance has recently been used extensively in spasm and progressive thrombosis of arteries, but so far as they know it has never been used in ischemia consecutive to arterial embolism, save in two very recent cases of their own. The first patient was a woman of 37 with a mitral lesion and asystolia. There was an embolism in the lower part of the left lower extremity with coldness and cyanosis. There was no edema. The leg was quite powerless. The right lower extremity showed edema but the temperature and color were normal. The embolism was manifest. In addition to the usual treatment of heart failure acetylcholine was injected by the intramuscular route, one half a gram (71/2 grains) twice daily. In the evening when only one injection had been given, the temperature of the limb was nearly normal, but the cyanosis had not been changed. The following morning the color of the skin had become normal and the patient was able to move her toes. On the next day edema set in. After a few days of freedom from the original symptoms, cyanosis and coldness returned, treatment was resumed but the general state of the patient was now very grave and death took place from heart failure. Autopsy was not permitted. The treatment had no effect on the blood pressure and the improvement must be attributed to the action of the drug on the collateral circulation. The second patient was a woman of 29 with a mitral lesion and partial decompensation. She developed suddenly an embolism in the artery of the right lower extremity derived probably from phlebitis of the opposite limb. As a result there was progressive dry gangrene of the right foot and leg. The patient in addition to treatment of heart failure received acetylcholine. The result was remarkable, for the symptoms of gangrene all receded, but unfortunately the patient developed an embolism in the brain and succumbed to coma in a few days. It is impossible to say whether the whole foot could have been saved in case of survival, but the loss should have been minimal.-Le Progrès Médical, April 12, 1930.

The Dietetic Treatment of Skin Tuberculosis.—M. Gerson of Cassel devotes an article in the Klinische Wochenschrift for April 12, 1930, to an analysis of several criticisms of his method of treating tuberculosis by a salt-free diet. Wichmann had said that the smooth, dry, squamous form of lupus gave no response to this method, and that he had not seen a single

instance of a cure of the disease in the sense of the disappearance of all the lupus nodules. On the other hand Bommer asserted that the cure of lupus by the dietetic treatment was an absolute fact. Jesionek stated that the tuberculous lesions of the skin disappeared entirely. The author himself says that all his patients were promptly and completely cured with only one exception. This was a farmer's wife who had extensive areas of lupus vulgaris on the nose and cheeks. During the first six weeks of treatment the progress toward recovery was most satisfactory, but then there came a halt. On questioning the woman the writer learned that she still adhered strictly to the dietary regulations, but had begun to treat herself to "a little" salt. She said she wanted the salt, and was content with the improvement already reached. Gerson reports several cases in which a rapid healing was obtained by his salt-free diet and repeats that during the 18 months he has been using the method he has yet to see a case of failure.

Wichmann replies to Gerson in the same issue, saying that a year and a half is too short a time to warrant the assertion of a permanent cure, and repeats his statement that to call the dietetic method an absolute cure for all forms of tuberculosis is not in accordance with the facts.

Nasal Sinus Disease in Small Children .-L. W. Dean states that in considering the etiological factors concerned in the production of sinus disease in children one must think of deficient diet, poor hygiene, allergy, metabolic disturbances, climatic conditions, especially lack of sunshine, swimming, endocrine disturbances, nephrosis, diseased tonsils and adenoids, nasal blockage, and infection, especially in contagious disease. It is more important to know what prepares the tissues for infection than to know the infecting organism. Vitamins and hygienic measures are the most important factors in keeping up immunity or resistance. The first step in treating sinus disease in young children is the eradication of the cause. Only by taking into consideration all the systemic etiological factors above mentioned can one possibly treat the condition. The securing of a painstaking history is of the greatest importance. The second step is the examination by the pediatrist, including a complete report as to the child's metabolism, as to endocrine disturbances, as to allergy and all things which have any bearing on the condition. Diet, hygiene, and clothing must be regulated; allergy, if present, must be controlled. It is quite essential that these children

should lead an out-door life and do all things that normal children do, including swimming. with the precaution that the head be kept out of the water. Diseased tonsils and adenoids should be removed. Only rarely is it necessary to operate upon a septum. During an acute exacerbation ephedrine is especially beneficial. When polyps are present an allergic basis should be carefully sought. Polyps should be removed in the usual way. If they return, cauterization with trichloracetic acid or other simple measures, or the use of radium, should be considered. If an apron of lymphoid tissue on the wall of the pharynx persists in spite of sinus treatment this should be attacked with the x-rays. Operation on the nasal sinuses of children, other than meatal drainage of the maxillary sinuses, is very rarely indicated.—Laryngoscope, May, 1930, x1. 5.

Foods in the Solution of the Goiter Problem. -William Weston, writing in the Southern Medical Journal June, 1930, xxiii, 6, asserts that iodine deficiency in its organic relations is probably America's foremost public health The United States Public Health problem. Service places two-thirds of the United States in the goiter area. He has been convinced, as the result of careful observation, that goiter is practically nonexistent in South Carolina. From this he inferred that fruits and vegetables locally grown contained a high percentage of iodine. In order to study the subject a research laboratory was established to make complete chemical analyses of all foods grown in South Carolina, which are used in human and animal diets. These analyses soon demonstrated that South Carolina fruits and vegetables contain enormous amounts of iodine, as well as of manganese and iron. The green, leafy vegetables are by far the best sources of these elements. The tomato is destined to play an important rôle in the science of nutrition. Turnip tops and cabbage are poor sources of copper and manganese, but are good sources of iodine. A comparison of the milk produced in South Carolina with that of Wisconsin, Michigan, and some of the other prominent dairy states shows a surprising difference in regard to the iodine, iron, and manganese content. Milk produced in South Carolina from cattle fed on native foods runs about one thousand parts per billion of iodine as against less than one hundred parts for the Mid-Western The solution of the goiter problem, in the author's opinion, will be accomplished through a food supply rich in iodine, iron, manganese, and copper and probably other important mineral elements.

# LEGAL

## THE INSTITUTE OF LAW OF JOHNS HOPKINS UNIVERSITY

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

The law has lagged far behind medicine in the adoption and application of scientific research as an aid in the ascertainment of truth. with a view to a proper solution of the respective problems that are ever present in these two great professions. Within the last decade, there has been a notable interest by those outside the legal profession in the administration of justice in this country. The public eye has been focused upon the workings of our courts, and the voice of public opinion, both within and without the profession, has again and again been heard in a scathing denunciation of the antiquated methods by which our laws are administered. One of the most eminent members of the Bar of the City of New York summed up the situation in this language:

"The opinion that the law is unnecessarily uncertain and complex, that many of its rules do not work well in practice, and that its administration often results not in justice but in injustice is general among all classes and among persons of widely divergent political and social opinion."

It is, then, with genuine satisfaction that we are able to say that an earnest and scientific attempt is being made by a distinguished group of men to ascertain the true situation with respect to the conditions now obtaining in the administration of justice in America. The Institute of Law of Johns Hopkins University has undertaken this all-important task. Institute has assembled a small but extremely able group of men whose objective is the gathering of information necessary for the shaping of sound reform measures in the law. Fortunately, this movement is generously endowed and is under the able leadership of Walter Wheeler Cook who, after teaching mathematics at Columbia University, entered the legal profession and became Professor of Trusts at Yale University; Leon Carroll Marshall, distinguished economist of the University of Chicago; Hessel Edward Yntema, Professor of Roman Law and Conflicts at Columbia University; and Herman Oliphant, Professor of Contracts and Trade Regulations at Columbia University. These gentlemen are all resident at Johns Hopkins University, and

have assembled a splendid staff to assist them. There will be no law school curriculum associated with the plan, and most of the assistants who are engaged in the work of the Institute will be members of the Bar already trained in other schools.

The purpose of the Institute of Law is to find out, not what the law is, but why it is Complex as are the legal structures of the nation, the states and local municipalities. it is apparently the business of no one to seek to determine whether or not the law is achieving the purposes for which it was created. Legislators are busy in their enactment throughout the nation of thousands of statutes and regulations. Lawyers are engaged in seeking specific application of the law to the problems of their individual clients. Students are preoccupied with their attempts to learn the elementary principles of the law. Hence, there has been no determined effort to investigate and report upon the obvious defects in the workings of our laws. Many old rules have been preserved despite their inadequacy when they come in contact with modern con-Tremendous social, political and economic changes have been wrought by the years. The country, highly cosmopolitan in its nature, has often been forced to patch and piece with legal device to cover specific situations.

An accurate study of the law involves the investigation not only of legislative and judicial bodies, but of the vast number of administrative boards and commissions and councils of arbitration which have grown up in recent years. To survey the vast field of law in the United States, or even attempt to seek out scientifically the facts upon which an accurate statement of present conditions may be based, requires the undivided attention of able leaders, as well as a sufficient sum of money to carry on their work. Fortunately for this investigation, Johns Hopkins has assembled a distinguished group of men fully qualified for their task, and thanks to its generous donors, it has also a fund to carry out the objective of this movement.

As a first step in the solution of the problems under advisement, there was sent to every member of the Bar of the City of New York a questionnaire accompanied by a letter which states, among other things, the following:

"The Johns Hopkins University is inviting the lawyers of New York, beginning with those in New York City, to participate in this undertaking by supplying basic data in the form of information as to one or more pieces of litigation each has handled. The accompanying schedule of questions is being sent to all members of the Bar with a request for answers from those who are handling or are in touch with litigation and for the information of those who are not.

"New York has been chosen as the first state to be studied because the procedural systems of many states were modeled on that of New York and because more legal business is handled by its courts than by those of any other state.

"An accurate knowledge of how the machinery is working at every stage of a proceeding is essential and this can be obtained only by ascertaining what occurs in a great many actual cases. The real purposes for which our procedural rules are used and the practical effects of their use are vital matters not to be found in court records. These records are not to be neglected, but, in order to make the study thorough-going and practical, the data in public records must be supplemented by information which can be obtained only from the lawyers themselves. For that reason, full information as to actual cases is being sought from lawyers. It will be observed that the name of the case to be selected by each of them is not asked for in the enclosed questions. In consequence, it has been necessary to ask for certain items of information, which would be obtainable from court records if the names of the cases were known.'

Some idea of the nature of the information sought to be elicited by the Institute may be shown from a few of the inquiries set forth in the questionnaire:

Were you attorney for the plaintiff or the defendant?

A statement of the facts of the case is requested.

What caused the dispute involved in this litigation to arise?

Conciliatory efforts to effect a settlement and to avoid or terminate litigation.

A history of the pleadings is then requested, followed by a history of the trial, including a question as to what expert testimony was used, and what was its practical value.

A description is asked of any steps taken by either side to get the hearing on any motion or the trial before a particular judge.

If there were an appeal from the judgment, a detailed list of questions is to be answered.

What valuable business relationships of the parties if any, were destroyed (a) by the controversy and (b) by the litigation?

State the steps taken to collect the judgment

or to secure other relief granted.

The outcome of the case.

What was the last step in finally disposing of this case and when was it taken?

What was your client's total outlay in connection with this litigation?

These questionnaires were sent out on March 1st, 1930, and it is interesting to note that Professor Herman Oliphant in a letter to the New York Law Journal under date of May 26th, 1930 says:

"On March 1, 1930, these questions were sent to all lawyers in New York City. They were accompanied by a letter signed by leading lawyers and judges requesting cooperation. It has been very encouraging to note the interest with which the Bar has received these questions. Lawyers have heard on innumerable occasions that law reform is their personal problem, and that they have a professional duty to assist in the improvement of legal methods. They seem to realize that here is a real opportunity of translating these words into action.

"Sometimes the busy lawyer at first hesitates before answering these questions. He feels that the court records should be examined instead of encroaching upon his valuable time. But he does not have this feeling when he comes to realize that the court records give but a meagre outline of actual conditions and that he is being called upon to contribute the story of only one or two cases. He may feel that the things asked for are matters between him and his client. But he soon sees that the inquiry relating to a closed transaction does not ask for the name of the case, and that even his own name will be kept in the confidential files of the university."

The legal survey thus contemplated by the Institute will be done in a painstaking manner, to the end that the conclusions reached will be based on as complete an investigation as it is possible to make. The committee that has undertaken this work will merit the everlasting gratitude of every citizen of this country, if it can assist in eradicating the numerous defects in the administration of justice. Not only the legal profession, but every citizen who has the welfare of his country at heart, eagerly awaits the findings and proposed reforms of this committee upon the conclusion of the survey which this Institute has now under way.

# HOUSE OF DELEGATES

## MINUTES OF ANNUAL MEETING

The Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Hotel Seneca, Rochester, on Monday afternoon, June 2nd, 1930. Speaker, Dr. John A. Card; Secretary, Dr. Daniel S. Dougherty.

#### 1. COMMITTEE ON CREDENTIALS

The Speaker: The first order of business is the report of the Committee on Credentials; Dr. Dougherty.

The Secretary: Mr. Speaker and Gentlemen, the Committee on Credentials has the pleasure of reporting that there is no duty for it to perform, as there are no disputed delegations.

The Speaker announced that the Secretary would call the roll by Counties for the purpose of determining the presence of recognized delegates.

The Secretary then called the roll by Counties. (For roll call by members, see Section 94.)

The Speaker: There being a quorum present, we will proceed to the regular order of business. The next item of business will be the reading of the minutes of the previous meeting.

#### 2. Approval of Minutes

The Secretary: I move that they be adopted as published in the New York State Journal of Medicine of July 1, 1929, page 824.

Motion seconded, and carried,

#### 3. Reference Committees

The Speaker: I will now ask the Secretary if he will read the list of Reference Committees, to act at this session of the House of Delegates.

The Secretary read the following reference committees: (See also Journal May 15, page 603).

Reference Committee on the Report of the President: Charles H. Goodrich, Kings, Chairman; Henry J. Noerling, Columbia; John J. Beard, Schoharie; Luzerne Coville, Tompkins; Joseph P. Henry, Monroe.

ville, Tompkins; Joseph P. Henry, Monroe.
Reference Committee on the Reports of the Secretary, the Council, Councillors and the Board of Censors: Edward C. Podvin, Bronx, Chairman; Luther C. Payne, Sullivan; Edwin A. Griffin, Kings; Horace M. Hicks, Montgomery; Samuel J. Kopetzky, New York.
Reference Committee on the Reports of the Treasurer and Trustees: Charles C. Trembley, Franklin, Chairman; W. Grant Cooper, St. Lawrence; Cornelius J. Egan, Bronx; Wendell C. Phillips, New York.
Reference Committee on the Report of the Committee on Legislation: Walter T. Dannreuther, New York, Chairman; Joseph B. Hulett, Orange; John J. Rainey, Rensselaer; Jacob A. Keller, Bronx; Frederic E. Elliott, Kings.

Reference Committee on New Business-C: Terry M. Townsend, New York, Chairman; John E. Jennings, Kings; Ralph T. Todd, Westchester; William J. Lavelle, Queens; Adelbert B. Allen, New York.

# 4. Address of the President

The next order of business is the address of the Presi-

The Secretary: Owing to the fact that this has appeared in print in the New York State Journal of Medicine, of May 1, 1930, page 495, I would ask the privilege of making the motion that it be referred, without reading to the proper committee for report later.

The Speaker: It is so ordered, without a vote.

#### 5. Annual Reports

The Secretary: Moved, that as all the reports have been printed in the May first issue of the Journal and distributed to the delegates, that they be referred to the respective reference committees as printed.

Motion seconded, carried and so ordered.

The Secretary: Certification of Specialists I would like to supplement the report of the Executive Committee by saying that at the last meeting, which was pleid after the report was printed, the recommendation the obtaining of Delegates, passed last year, regarding the obtaining of a law or a ruling of the Regents, certifying specialists, was referred to a special committee consisting of Drick, who will report to the Executive Committee at its next session. (See Section 53).

The Speaker: It is so ordered. I will now ask the various reference committees if they will proceed to their several duties.

Dr. Farmer: Mr. Speaker, as Chairman of the Committee on Public Health and Medical Education, I would like to submit a supplementary report.

## 6. Unfinished Business

The Speaker: That will be referred to the appropriate committee. Now, is there any unfinished business arising from the minutes of the last session, Mr. Secretary, have you anything on your desk?

The Secretary: No, sir.
The Speaker: There being none, we will proceed to

the matter of new business.

Dr. Bonnar stated that there were certain resolutions which had been passed by the Erie County Medical Society on the 19th of May, which he desired to read and have action taken.

# 7. Economics and (8) Officers Opposing Official Action

Dr. Kasmierczak, of Eric County: Read the following resolutions:

1. RESOLVED. That the New York State Journal of Medicine devote more space to economic matters in preference to scientific articles.

2. Resolved, That the Medical Society of the State of New York, through its Secretary, obtain an annual report, if possible, of the medical beneficiaries under the

compensation law.

3. Resolved, That any officer or member of a committee of the Medical Society of the State of New York, or any officer or member of a committee of a County Medical Society shall first resign his official position before opposing any resolution or measure which the State Society or his County Medical Society has adopted. (See Section 60.)

4. Resolved, That the activities of members of the Committee on Medical Economics of the Medical Society of the State of New York, as shown by opposition to the bill for free choice of physician in compensation cases and in other matters affecting the economic side of medical practice calls for an entire new personnel and shall not be chosen from physicians who are connected with industrial plants. (See Section 61.)

The Speakers This will be referred to Reference

Committee on New Business A.

9. Prescriptions for Alcohol and Narcotics

The Secretary presented the following resolutions from Dr. Van Etten of Bronx County.

WHEREAS, The confessions of the penitent to his priest, the communications of the client to his counsel, and the confidences of the patient to his physician, have been held inviolate from remote ages and have been jealously guarded by the courts, and

WHEREAS, The regulations of the Volstead Act for the enforcement of the 18th Amendment and the provisions of the Harrison Act require physicians to state the diagnosis of the disease or ailment of the patient on the stub of every prescription they write for alcohol and on every prescription they write for narcotics, and

WHEREAS, The stubs of all prescriptions for alcohol must be surrendered to Prohibition Commissioners for inspection by them and their clerks and all prescriptions for narcotics are open to inspection by Federal Agents,

now, therefore,

BE IT RESOLVED, That the Medical Society of the State of New York hereby voices its protest against those portions of the prohibition and narcotic laws which deprive the citizen of his age-old right to privacy regarding his diseases and ailments, which compel the physician to betray the confidential communications of his patient, to violate the ethics of the medical profession and to violate the law of the State of New York, and

BE IT FURTHER RESOLVED, That the Delegates of the Medical Society of the State of New York to the American Medical Association be, and hereby are, instructed to present the above Resolution to the House of Delegates of the American Medical Association for action at its next meeting in Detroit.

The Speaker: Referred to Reference Committee on New Business B. (See also Section 66. For action, see Section 76.)

10. STERILIZATION OF THE UNFIT

The Secretary read the following resolution from the Seneca County Medical Society:

WHEREAS, The number of idiots, feeble-minded and insane individuals are assuming each year an increasing proportion, and

WHEREAS, Such individuals are themselves non-producing and a charge upon the State for their support, and

WHEREAS, Such conditions are becoming almost intolerable in regard to social, financial and hygienic aspects, it is hereby

RESOLVED, That the Medical Society of the State of New York, acting in the interest of humanity and for the prevention of further increase in the birth and propagation of mental defectives, does hereby place itself on record as favoring the sterilization of lunatics, idiots, the feeble-minded and epileptics. Such sterilization to be performed in suitable cases, subject to proper medical and legal supervision. And be it

FURTHER RESOLVED, That a committee of the Medical Society of the State of New York be instructed to draft a bill, embodying the above resolutions, for presentation to the Legislature of the State of New York at its next session.

The Speaker: Referred to Reference Committee on New Business, C. (For action, see Section 67.)

## 11. QUALIFICATIONS FOR PUBLIC HEALTH POSITIONS

Dr. Browder of Kings presented the following resolution:

WHEREAS, in the early days of health work, health officers were practicing physicians, or sometimes laymen,

Whereas, today special training leading to degrees in

public health is available; now, therefore, be it RESOLVED, That the Medical Society of the State of New York, through its State and County Committees on Public Health and Public Relations, advise the public of the need of special training and aptitude for public health

work, and be it further RESOLVED, That these committees inform appointing individuals and boards that specially qualified personnel should be appointed to positions involving responsibility for community health; be it further

RESOLVED, That nothing in this resolution is intended

to displace or disparage present officers who, through long experience, have acquired much of the information which is now being given by formal instruction, but that the only intent of the resolution is to provide for filling vacancies and newly created positions in health work.

The Speaker: Referred to Reference Committee on

New Business B. (For action, see Section 74.)

# CHOICE OF PHYSICIAN

Dr. Sadlier introduced the following resolution:

WHEREAS, the House of Delegates, at its last meeting, approved of an addition to the Workmen's Compensation Law authorizing the injured workman to select his own physician or surgeon, and

WHEREAS, such an amendment was proposed to the last

legislature and frowned upon by it, and

WHEREAS, at the hearing given this amendment representatives of labor and the workman made no effort to support the bill, and

Whereas, there is nothing in the law at present which

prevents the injured workman from selecting his own physician, and

WHERFAS, a survey made by the Department of Labor of the treatment stations in New York City revealed that many are unsanitary and madequately equipped, and

WHEREAS, no evidence has been brought forth to prove that the injured working man is not properly and promptly cared for under present conditions

BE IT RESOLVED, that the House of Delegates recon-

sider the action taken a year ago

The Speaker That will be referred to Reference Committee on New Business A

#### 13 GOVERNOR'S SPECIAL COMMISSION TO REVISE LAWS

Dr Sadher I have one other resolution, Mr Speaker WHEREAS the medical profession has cooperated in the development of the public health program adopted by the state in recent years, and

WHEREAS, the profession is satisfied that the public has profited greatly by its efficient administration, and WHEREAS, it believes there is need for re statement of

the program with suggestions for its revision in accordance with the advancement of scientific knowledge and

the prevailing social and economic conditions, therefore Be It Resouven, that the Medical Society hereby expresses its approval of the action of the Governor of the State in Creating the Special Health Commission to study and report to him upon the working of the Public Health Law, and offers him such assistance as it may have opportunity to render, and

BE IT FURTHER RESOLVED, that the Society realizes the social trend of today in which the State is assuming greater responsibility for the provision of adequate medical care for the indigent and wishes to assure the Governor that it will maintain its traditional spirit of cooper ation in providing the public with the best medical ser

VICE, and
Br It Still Further Resolved that the Commission be requested in preparing such recommendation as it may choose to make as a result of the study, to respect the traditional strategic relationship that has always existed in well regulated instances between physician and patient, and not to permit the state in its impersonal way to supplant the family physician

The Speaker Referred to Reference Committee on New Business C (For action, see Section 70)

Dr Woodruff, of Eric Presented the following resolution

#### 14 TREE CHOICE OF PHYSICIAN

RESOLVED, That a special State Committee be appointed composed of members who have declared themselves in favor of free choice of physician in compensation cases with power to act in the several counties of the State for the purpose of unifying all interests in support of an amendment to the Workmen's Compensation Law which

amendment to the Workmen's Compensation Law whiten shall permit injured employees the privilege of selecting their physician if they so desire, and be it further Risolven that each County Medical Society in the State shall recommend a volunteer representative from its members to be appointed to said State Committee and such volunteer member shall become chairman of the county sub-committee should the County Medical Society see fit to increase the personnel of its sub committee. The Speaker Referred to Committee on New Busi-

#### 15 COMMERCIALIZATION OF MEDICAL PRACTICE

Dr Fisher, of Oneida Presented the following resolu-

WHEREAS the following card appeared in the last is sue of the New York State Medical Journal under the heading "Classified Advertisements' as follows

"Registered Optometrists or Physicians wanted to take charge of optical department in chain stores. Positions open in Binghamton, Schenectady and Utica. Exceptional

opportunities offered to men with New York registra tions Preferably men of middle age Address Optom etrist Box 1204 Providence R I"

THEREFORE Be it resolved that this House of Delegates of the Medical Society of the State of New York considers it a poor policy and establishing a bad precedent in publishing in the Journal any advertisement which will lower the dignity of the practice of medicine, and would suggest to the Advertising Manager and Editor that more care should be taken in admitting advertisements of this nature

AND BE IT FURTHER RESOLVED That this House of Delegates does not consider it good form for any member of the Medical Society of the State of New York to commercialize the practice of his profession by entering the employ of chain stores or department stores in profes sional mainer, and that by doing so he subjects himself to censure by his County Society or the State Society

The Speaker Referred to Reference Committee on New Business C (For action, see Section 71)

#### 16 Practice of Medicine by Corporations

Dr Messing, of New York presented the following

WHERLAS, There have recently sprung up a number of organized groups practicing medicine under an incorpor ate name be it resolved that the House of Delegates of the Medical Society of the State of New York bring a test case before the higher courts to test the legality of these corporations practicing medicine under the laws of

the State of New York

The Speaker Referred to Reference Committee on
New Business B (For action, see Section 77)

#### 17 PAY CLINICS

Dr Ferber, of New York Presented the following resolution

WHEREAS, in the City of New York certain pay clinics are operating under the provisions of the Dispensary Law,

WHEREAS these pay clinics are charging patients who come there for treatment an amount equal to that which would ordinarily be paid by the patient to a private physician and

WHEREAS the said paid clinics operating as aforesaid are endangering the economic life of the individual

Now, Be It RESOLVED, That the Medical Society of the County of New York desires to register its protest against pay clinics operating in the manner hereinbefore de scribed

The Speaker Referred to Reference Committee on New Business C (For action see Section 69)

The Speaker Are there any committees ready to re

#### REFERENCE COMMITTEE ON PUBLIC RELATIONS REPORT

Dr Fisher Your Reference Committee on the Report of the Committee on Public Relations (Journal, May 1, Page 516) respectfully reports as follows

Our report must necessarily be one of commendation The many and varied changes which have taken place during the past few years and probably will continue during the years to come, in relation to the physician and public organizations both state and privately controlled, proves the value and wisdom of having a Committee on Public Relations

We have arrived at a time when it is utterly impossible we nave arrived at a time when it is utterly impossible and not advisable for any individual physician to cope with these questions alone, even in our smaller communities or larger centers of population. These questions must be studied so collectively or in mass as is the tendency of the times in all great public or private interests. Well does your Committee 513, 'There was once a

time when every man was in control of his own relationship to others but in these days groups of people work together and individual relationship no longer can be

depended upon as a professional guide."

It should be a source of gratification to this House of Delegates to know practically all of the County Medical Societies have established a Public Relations Committee and we commend the efforts of your committee in holding meetings with the several County Committees at the annual District Branch meetings, thus keeping in close personal touch with all sections of the State.

The investigation suggested by the House of Delegates as to whether many hospitals prevent physicians and surgeons from collecting for services rendered industrial patients admitted to the wards has been thoroughly considered and should be endorsed by this House, and we would again suggest to the Committee they continue the work in New York City until changes are made which will give to every practitioner the opportunity to receive proper recompense for his labor.

# 19. RURAL HOSPITALS

Your committee has given the study of the rural hospitals and health centers due consideration and the rules and regulations which they have formulated are broad and liberal from the standpoint of both the physician and laity and should receive our most hearty support.

We are in full accord with the Council in endorsing the report of the Committee on Public Relations as expressing the sentiments of the Medical Society of the State of New York and delegate to the Committee the power to take such action as will be effective in putting the following recommendations in force:

"That all state aided county general hospitals shall have

an open staff.
"That hospital standards shall conform to the requirements of the American College of Surgeons and of those

of the American Medical Association.
"That the Board Managers shall consist of five members, at least three of whom shall be physicians in good standing and members of their county medical societies. They shall be selected by the county medical society in accordance with the law prescribing the method of nominating the physician members of a county board of health.

"That the Committee on Public Relations of the Medical Society of the State be given the power to carry on negotiations with the State Department of Health regarding the organization of State aided general hospitals and to report progress from time to time to the Executive Committee or to the Council or the House of Delegates."

We do not consider a further resolution by this House necessary as the Council is the representaive body of the

House of Delegates when not in session.

It is very satisfactory to note the cordial relationship which exists between the Public Relations Committee and the State Departments of Health, as well as all the lay organizations with whom they have been called upon to confer and we would suggest a continuation of the monthly letter to the President and Secretary of each County Medical Society and the Chairmen of all Public Health and Public Relations Committees.

We are of the unanimous opinion that the Medical Society of the State of New York is to be congratulated in having a committee composed of such energetic and painstaking personnel of physicians who are all busy men, sacrificing a great amount of their own valuable time to the mutual interest of the entire profession and

the public at large.

I move the adoption of the report. Motion seconded and carried.

20. CHARGES TO INDUSTRIAL PATIENTS IN FREE WARDS Dr. Fisher: Your Reference Committee on the Report of the Report of Committee on Public Relations has Where resolution to present: WHEREAS, The Municipal Charter of New York City

prevents attending physicians from making the charges for services rendered industrial patients while under treatment in the wards of general hospitals, thus rendering an injustice to the physician in charge,

THEREFORE, BE IT RESOLVED By this House of Delegates of the Medical Society of the State of New York that the Corporation Counsel of the City of New York be petitioned to aid in the revision of the Municipal Charter so as to allow suitable fees to be rendered by such attending physicians for medical and surgical services, and be it

FURTHER RESOLVED that the Public Relations Committee be instructed to present this Resolution to the Corporation Counsel, or other powers as they may deem best and to use all honorable means in securing the desired revision of the Municipal Charter.

The Speaker: Referred to Committee on New Business C. (For action see Section 68.)

# 21. CHOICE OF PHYSICIAN BY INJURED WORKMEN

Dr. Ferber, of New York: Presented the following resolution:

WHEREAS, under the terms and provisions of the Workmen's Compensation Law, the injured employee is deprived of a right to select his own physician, and

WHEREAS, this situation likewise obtains in cases coming within the jurisdiction of the State Insurance Fund, now be it

RESOLVED, That the New York County delegation request the Medical Society of the State of New York through its proper committee to confer with the Commissioner of Labor with a view to enlisting the support of the said Commissioner of Labor in cases coming un-der the jurisdiction of the State Insurance Fund, to permit the injured employee to select in the first instance a physician of his own choice,

The Speaker: Referred to Reference Committee on New Business A. (See Section 62.)

# 22. PAY OF PHYSICIANS IN PUBLIC EMPLOY

Dr. Messing, of New York: Presented the following resolution:

Whereas, employed physicians in the State of New York are paid on the average less than \$5.00 an hour,

Whereas, the services rendered by such physicians are reasonably worth a minimum of \$5.00 per hour. Now, be it.

RESOLVED, That the New York County Delegation expresses the conviction and opinion that employed physicians shall be paid a minimum fee of \$5.00 per hour.

The Speaker: Referred to Reference Committee on New Business B. (For action see Section 75.)

# 23. President's Address-Woman's Auxiliary

Dr. Goodrich: Your Reference Committee on the President's Address, begs leave to report in part as follows:

1. "Women's Auxiliary. We recommend that a special committee be appointed to consider the question and advisability of a Women's Auxiliary from every standpoint, said committee to report to the Executive Committee."

I move the adoption of this recommendation. Seconded and carried.

# 24. CANCER PREVENTION

2. "Cancer Prevention. We recommend that a special committee be appointed to provide lectures for the public, presenting these lectures wherever possible in co-operation with cancer prevention groups already organ-ized. Wherever these lectures are given it should be stated that they are given under the auspices of the State Medical Society. We also recommend that this committee be constituted as a sub-committee of the Committee on Public Health."

I move the adoption of this recommendation. Seconded and carried.

#### 25. Executive Committee Meetings Program

3, "Advance program of Executive Committee Meet-

ings." We recommend that this recommendation be adopted.

Motion seconded.

Dr. Kevin, of Kings: Moved to amend by inserting the words "so far as practicable," which amendment was accepted by the Committee.

The motion was made for adoption of the resolution as amended, was seconded and carried.

#### 26. HISTORICAL RECORDS

4. "Historical Records. We recommend the adoption of this recommendation.

This has to do with the collection and preservation of museum records, and specimens.

Motion seconded.

The Speaker: Dr. Goodrich, will you please read the paragraph on the President's Report, relating to this matter?

Dr. Goodrich: "There is again brought to the fore the proposition of a new State Museum building in Albany, wherein might be housed a wonderful collection of various articles portraying the history of medicine in this

State and perhaps in this country.
"The Director of the Museum is anxious to assemble such a collection and I would offer the suggestion that a special committee might be appointed whose duty it would be to obtain old instruments, books and implements, etc., during the coming summer and arrange with the director for such to be put on display as a 'Collection loaned by the Medical Society of the State of New York,'

and by individual members.
"Many of our County Societies have old records, which are now subject to fire hazards. These should be housed perhaps in a central fireproof vault. Or at least copies of them should be made and sent to our Secretary's office for future preservation."

Dr. Phillips, of New York, spoke on the possible cost

of this undertaking, and suggested that an appropriation would have to be made therefor.

A vote was taken and the motion was carried.

#### 27. STATUS OF VICE-PRESIDENT

5. "The Vice-President and Executive Committee, We recommend the adoption of this recommendation. This refers to the attendance of the ranking Vice-

President at Executive Committee Meetings.

It involves a small change in our by-laws.

The Secretary called attention to the fact that a resolution of the House of Delegates usually takes the place of an amendment to the by-laws, and stated that most of, the work of the House of Delegates should be done in the form of resolutions, which makes them flexible.

Motion seconded and carried.

#### 28. Bond of Those Appealing to Censors

6. "Censors. We recommend the adoption of this section, the size of the bond to be suggested by the Counsel." (Journal, May 1, Page 497.)

I move the adoption of this recommendation,

On motion duly seconded and carried the recommendation of this committee was referred back to the committee, for further consideration.

#### 29. PRELIMINARY REPORT OF PROCEEDINGS OF THE House of Delegates

7. "Reports of Proceedings of the House of Delegates. We recommend the adoption of this recommendation." The Speaker: Will you please state what that recommendation is?

Dr. Goodrich: The recommendation is that the Speaker give a brief resumé of the proceedings of the House of Delegates to be given to the members of the House at the end of the meeting.

The Speaker: Will the Vice-Speaker please take the chair?

The Vice-Speaker then took the chair.

The Speaker: How is it possible to give so soon after adjournment a resume of what has taken place in the House of Delegates? It is impossible and unnecessary, for the minutes are fully recorded and published in the JOURNAL within a month after the meeting. I recommend that the resolution be defeated.

Dr. Phillips, of New York: I move that this portion of the report of the Reference Committee be tabled.

Motion was seconded and carried-65 to 17.

#### 30. REIMBURSEMENT FOR EXPENSES

Dr. Goodrich: 8. The expenses of officers and com-The committee favors the recommendation for reimbursement of hotel and necessary incidental expenses for members traveling on society business, and urges the adoption of the President's recommendation.

I move the adoption of this recommendation; motion

seconded.

Dr. Rooney, of Albany: Who is to say what is necessary and unnecessary expense? I would not object to this recommendation if a limit were set to the total expenses in a year. This is necessary, as the income of the society is limited. I move that this section be referred back to the committee for further consideration,

Dr. Goodrich: I recommend that the matter be referred to the Board of Trustees.

The Secretary: A point of order; this cannot be re-ferred to the Board of Trustees, The Executive Committee is the proper referee. I am in accord with Dr. Rooney in recommending that the matter be referred back to the Reference Committee.

Dr. Rooney, of Albany: I agree with the Secretary. Dr. Goodrich: I would like to ask for information in regard to the functions of the Board of Trustees and the

Executive Committee.

The Speaker: The Executive Committee and not the Board of Trustees is the proper referee in this matter. Dr. Coville, of Tompkins: Moved that the words "Executive Committee" be substituted for the words "Board of Trustees."

Dr. Goodrich: I would like to call attention to Chapter VI, Section 2, of the By-Laws.

The Speaker: The resolution is to the effect that the

Trustees approve the expenses.

The Secretary: I would like the Counsel's opinion on

The Counsel: There is no provision in the By-Laws by which the Board of Trustees can pass upon the resolution in question. I therefore sustain the resolution of the Chair.

Dr. Ludlum, of Kings: I move that this portion of the report be referred back to the Reference Committee. Motion seconded and carried. (See Section 49.)

#### 31. FORMAL ANNUAL MEETING

9. "Formal Annual Meeting. We recommend that the House of Delegates resolve to hold the annual meeting in 1931 at noon or some other designated daylight hour, in accordance with the recommendation of the President.

Your committee feels that it is wise, perhaps, to undertake this for one year, and see if the result is all that the President hopes for,

I move the adoption of this recommendation. Motion seconded. Voted upon and Lost.

4.

#### 32. Annual Banquet

10. "The Annual Banquet. We recommend the adoption of this section of the President's recommendation." Gentlemen, you probably all heard this, and all read this section, and you will note that in the third paragraph it says, "I would therefore suggest that the House of Delegates recommend to the Board of Trustees that a sufficient sum be appropriated in the next budget, perhaps \$2,000.00 or so much as is necessary to provide a social evening, including a banquet of a simple nature, perhaps, as a trial for our next annual session.

I recommend the adoption of this recommendation. Motion seconded. The motion to adopt this resolution

was defeated.

## 33. Conferences of Secretaries and Legislative CHAIRMEN

11. "Secretaries and Legislative Chairmen's Meetings. We recommend its adoption." Motion seconded and carried. (See Sections 41 and 47.)

## 34. Tri-State Conference

12. "Tri-State Conference. We recommend that the Conference be continued and that a sum of \$150.00 be approved for the coming year."

I move the adoption of this recommendation. Motion

seconded.

The Secretary moved as an amendment, that it be referred to the Executive Committee for the amount of the appropriation.

Amendment seconded.

The motion as amended, that the meetings be continued and the appropriation be referred to the Executive Committee, was placed before the House. (See Section 48.)

Seconded and carried.

## 35. DISTRICT BRANCH GOVERNMENT

13. "Special Committee on District Branch Work. We recommend its adoption." (Journal, May 1, page 498.)

Motion seconded.

The Secretary then spoke on this motion explaining and expounding the work of the District Branches and the District Branch Meetings. He urged against expenditure for District Branches, since he did not con-

sider it would be beneficial.

The Speaker explained that the motion was for the appointment of a Special Committee to study the District Branch Government, and report to the next meet-

ing of the House of Delegates.

The vote was taken and the motion was lost. (Journal, May 1, page 499.)

## 36. Councillors' Monthly Meeting

14. "Councillors and Executive Committee Meetings. We do not favor the adoption of this recommendation because of its impracticability and its extravagance in member's time and Society money.

We move that the recommendation be not adopted.

Seconded and carried.

## 37. Annual Address of President Elect to House of Delegates

15. "The Address of the President-Elect. We recommend the adoption of this section and add a recommendation that this address be given at the annual meeting in 1931."

The Speaker: Before we proceed with the recommendation I will ask if the President-Elect has anything

he wishes to say on this question.

The President-Elect: I believe that the recommendation made is a good one. If the President-Elect has done any work at all, and has come in contact with a sufficient number of the medical men, and with their organizations, if he has found out something of what is being and has been done in medicine, it is my opinion that he ought to have a definite opportunity to tell it.

Motion was seconded and unanimously carried.

Dr. Goodrich: That's all we have prepared so far. The Speaker: Are there any other committees ready to report?

# 38. Physicians' Cards in Daily Newspapers

Dr. Landsman of Bronx County presented the following resolutions:

(1) WHEREAS, The Bronx County Medical Society feels that publications in the foreign press of the city of New York of medical notices of individual physicians is contrary to the true spirit of medical ethics, and

(2) Whereas such publication has heretofore been condoned by the Medical Society of the State of New

York, therefore, be it

(3) RESOLVED, that the Medical Society of the State of New York express its disapproval of such publications and consider it contrary to the practices and principles of ethics of the medical profession.

The Speaker: Referred to Committee on New Busi-

ness C. (For action see Section 72.)

## 39. New York Academy of Medicine's Report on UNETHICAL PRACTICES

Dr. Landsman of Bronx County presented the following resolution.

Whereas, it has come to the attention of the Bronx County Medical Society that the New York Academy of Medicine has caused to be published in the lay press of the City of New York articles which were false; and

WHEREAS, these published articles convey to the public the impression that the medical profession as a whole were overcharging the public for medical service

and indulging in unethical practices; and

WHEREAS, these said published articles with their coincident state-wide distribution have given to the public the impression that the medical profession was foisting on the public physicians not truly qualified as specialists in their varied fields; and

Whereas, such publication methods tend to bring the body of the medical profession of the entire state of New York into disrepute.

THEREFORE, BE IT RESOLVED, that the Medical Society of the State of New York express to the New York Academy of Medicine its disapproval of such publicity methods.

The Speaker: That will be referred to Reference

Committee on New Business C.

# 40. Support of Public Health Measures

Dr. Thomson of Kings: There is circulating in Kings County a petition which is obtaining a considerable number of signatures, a copy of which I have in my hand, and which prompts the following resolution:

WHEREAS, Governmental officials and legislative bodies concerned with the protection of the public health are often petitioned to abolish existing health and welfare

protective measures, and

WHEREAS, the medical profession is frequently represented as being opposed to these destructive procedures from ulterior motives; Therefore, be it

RESOLVED: That the Medical Society of the State of New York, through its appropriate State and County Committees concerned with public health, public relations and legislative matters, use all legitimate efforts to arouse the interest of official and unofficial agencies concerned with the maintenance of health, to the end that they will obtain, by petition or otherwise, adequate appropriate support by the general public to counteract petitions now known to be in circulation for the purpose of creating sentiment favoring the repeal of such constructive health measures as vaccination against small pox, immunization against diphtheria, and the like.

The Speaker: Referred to Committee on New Busi-

ness A. (Report in Section 63.)

#### 41. REFERENCE REPORT ON COMMITTEE ON LEGISLATION

Dr. Dannreuther: Your Reference Committee on the Report of the Committee on Legislation have noted with interest and approval the activities of the Legislative Committee and the cooperative work of the Executive Officer.

We congratulate the Legislative Committee on its success in promoting the election of Dr. Grant C. Madill as a member of the State Board of Regents.

It is evident that the chiropractors almost succeeded in securing the necessary legislative support to insure the enactment of their bill this year and that it is essential that the medical profession solicit the active coop-eration of influential laymen in its future opposition to similar bills.

We suggest that the members of the Legislative Committee and the Executive Officer confer with the Commissioner of Labor early in 1931, so that the Medical Advisory Council bill may be certain of the necessary

support after its introduction.

We endorse the Legislative Committee's suggestion that the individual County Society Legislative Committees endeavor to interest powerful labor organizations in vigorously advocating the passage of the bill to allow the injured workman free choice of physician.

Your Reference Committee desires to stress the importance of action on the part of all the County Society

Legislative Committees.

After careful consideration of the formal suggestions made by the Legislative Committee to the House of Delegates, your Reference Committee submits the following comments and recommendations:

1. The State Society has previously ruled that no new medical legislation shall be initiated or introduced except through the Committee on Legislation and with the approval of the Executive Committee.

2. We recommend that the Chairman of the State

Legislative Committee be authorized to call a yearly meeting of the Chairmen of the County Legislative Committees and that this recommendation be referred to the Executive Committee for action. (See Section 33.)

We recommend that the Chairman of the Legislative Committee be empowered to enlist the aid and cooperation of educational institutions, organizations and interested welfare groups in our opposition to new cults and quack organizations.

I move the adoption of the report. Motion seconded and carried.

#### 42. PRIZE ESSAYS

The Secretary presented the following report from the Committee on Prize Essays: Gentlemen:

The Committee on Prize Essays begs to report that one essay was submitted for the Lucien Howe Prize, which after careful consideration by the Committee was not deemed worthy of the prize,

THOMAS H. CURTIN, Chairman,

I move the adoption of the report,

Motion seconded and carried,

The Speaker: Are there any other committees ready to report?

#### 43. SECRETARY'S REPORT

Dr. Kopeteky: Your Reference Committee on the Reports of the Secretary, Council, Councillors and the Board of Censors, has the honor in commenting upon the Secretary's Report to second his suggestion and express its appreciation of the efficient and willing work of the staff in the Secretary's Office.

#### 44. Appreciation of Legal Counsel

2. "The Committee expresses its deep regret at the

loss to the Society of the services of Mr. Lloyd Stryker and at this time suggests that the House of Delegates send him a vote of appreciation for all he has done for this Society and its members during his term of duty with it as its Legal Counsel."

I move the adoption of these recommendations.

Motion seconded, and carried, unanimously."
3. "It welcomes Mr. Brosnan and wishes him every success in his new affiliation with the Society."

#### 45. MEETING ROOMS AT HEADQUARTERS

"The Secretary's comment that the lack of room at the headquarters of the Society necessitated the absence of the clerks and stenographers, so that the Council and its committees might meet, has engaged our attention, and this Committee recommends that through the proper authorities a room be hired for its meetings, the expenses sent through proper channels and incorporated in the budget, so that the routine work of the Society be not handicapped and the Council have adequate facilities for its meetings.'

I move that the recommendation be adopted.

Motion seconded and carried.

#### 46. Appreciation of District Branch Officers

"The committee approves the work and commends the activities of the officers of the eight district branches. I move that the recommendation be adopted. Motion seconded and carried.

#### 47. Conference of County Secretaries

6. "Your committee feels that the conference of the Secretaries of the County Societies is of great moment and should be continued." I move the adoption of the recommendation, Motion seconded and carried. (See Section 33.)

#### 48. TRI-STATE CONFERENCE

7. "Your committee feels that the Tri-State Conference has possibilities of development, but feels that the Medical Society of the State of New York should have an authorized delegation to this Conference, and recommends that the delegates shall be the President of the Society and two others whom he shall designate. (See Journal, May 1, page 502.)

I move that the recommendation be adopted.

Motion seconded.

Dr. Rooney of Albany moved to amend by inserting a clause that in the event of the inability of the President to serve, that the First Vice-President act in his place.

Dr. Kopetaky: With the permission of the rest of the

Committee, I will accept that amendment.

The Speaker: The original motion as amended was put to a vote, duly seconded and carried. (See Section 34.)

#### 49. REIMBURSEMENTS FOR EXPENSES

"The question of the expenses of the Presidents of the District Branches is before us, and we feel that the duties required of such Presidents entail traveling and other expenses, which are truly the business of this Society, and we recommend that the proper body authorize the payment of these expenses of the Presidents of the District Branches in their official visits to the County Societies."

I move the adoption of this recommendation. Motion seconded and carried. (See Sections 30, 49

and 85,)

#### 50. REFERENCE COMMITTEES, APPOINTMENT AND MEETING

"This committee recommends, in order to facilitate the work of the House of Delegates, in line with surgestions in the Secretary's report of this year and last year, a change in our proceedings, namely, that the

Speaker, as is his custom, notify the members of the various Reference Committees of their appointments to such committees, and that all the Reference Committees shall meet on the morning of the day of the opening session of the House of Delegates, act on the reports of the officers and committees having to do with matters belonging to their committee which have been printed and are in the hands of the delegates some weeks prior to the meeting. These Reference Committees will then be ready to report on their work at the opening of the House of Delegates at its session in the afternoon. Extra and newer business can be taken care of by the Committees during the session of the House of Delegates.'

I move the adoption of this recommendation. Motion seconded and carried.

# 51. SARATOGA SPRINGS HEALTH RESORT

10. "Your committee heartily commends the development of the Saratoga Health Resort by the Governor's Special Committee.

## 52. Welfare Act of 1929, and Indigent Patients

11. "In reference to the resolutions presented by the Eighth District Branch (Journal, May 1, page 536), whose purport is that in the enforcement of the Poor Law (Public Welfare Act), passed April 12, 1929, medical aid shall be given to indigent families, your committee heartily recommends the resolution that the family physician be paid by the county for his services to the indigent patient.'

I move the adoption of this resolution. Motion seconded and carried.

## 53. Certification of Specialists

12. "Your committee has taken under consideration the supplementary report of the Executive Committee on the certification of specialists by the Regents of the State of New York (Section 5). Your committee feels that the idea of qualifying specialists to the public is a wise and proper procedure. Your committee knows that in some specialties there are already existing boards representing national societies of specialists. Your committee would rather move cautiously in recommending that the Regents be asked to take any steps in this matter until it has been more fully studied and its effects on the Medical Practice Act of the State better understood. We should be the last to do anything which might open the door to an amendment to the Medical Practice Act which we fought so long to secure. Your committee therefore recommends that this matter be referred to a committee for further study, for cooperation with existing agencies having similar purposes, and that before the society commits itself, the report of this committee shall come before this House of Delegates."

I move the recommendation be adopted.

Motion seconded and carried.

I now move the adoption of the report as a whole. Motion seconded and carried.

# 54. Reference Committees and Annual Reports

Dr. Ludlum, of Kings, presented the following amendments to the By-Laws:

Amend Chapter X to read as follows:

CHAPTER X. Section 10, At least one month before the meeting of the House of Delegates the Speaker shall appoint such Reference Committees as he shall deem expedient for the purposes of the meeting. Immediately after the organization of the House of Delegates he shall formally announce the appointments to the committees. Only members of the House of Delegates are eligible for appointment on the Reference Committees. Such committees shall consist of five members, three members constituting a quorum, and shall serve during the meeting at which they are appointed.

Section 11. Reports of Officers and Standing Committees shall be printed at least one month before the meeting of the House of Delegates and sent to the members of the Reference Committee appointed according to Section 10 for their preliminary consideration. All recommendations, resolutions, measures and propositions presented to the House of Delegates and which have been duly seconded shall be referred immediately to the appropriate reference committee.

Section 12. Each reference committee shall, as soon as possible, take up and consider such business as may have been referred to it and shall report when called

upon to do so.

The Speaker: This will lie over until the next session of the House of Delegates.

# 55. By-Laws-Amendment Regarding Trustees

Dr. Ludlum: I have another amendment to the By-Laws, which is simply a verbal correction, and not a change in the substance.

"In Article V of the Constitution the officers of the society are said to include 'five trustees.' Therefore Chapter 11 of the By-Laws should not say that: 'The House of Delegates shall be composed of - officers of the Society'-and 'Trustees.'

Therefore we offer as an amendment that, in Chapter 11 of the By-Laws this be omitted: "; (d) Trustee" and for the letter "(e)" be substituted "(d)."

Also in Chapter 111, Section 1, twice, and in Section 2 once that, "Trustee" be omitted as unnecessary."

The Speaker: That will lie over until the next session of the House of Delegates.

# 56. COMMITTEE ON DIPHTHERIA PREVENTION

Dr. E. E. Smith, of Queens: I wish to read the following report for Dr. Ratnoff, Chairman of the Special Reference Committee on the "Report of the Committee to form a plan to make toxin antitoxin available to every child in the State." (Journal, June 1, page 665.)

"That this House of Delegates" request the cooperation of the Departments of Health and Education and of Health and Education officials of every county, city, town, village or district of the State in a continuous campaign of education to reach those responsible for the pre-school as well as the child of school age."

I move the adoption of this recommendation.

Motion seconded and carried.

2. "That the filing of every birth certificate should be answered by a letter to the parents-which should advise them to take their babies to their family physician for instruction in disease prevention-for vaccination against smallpox and for immunization against diphtheria.

I move the adoption of this recommendation.

Motion seconded and carried.

3. "Your Reference Committee further recommends as a part of the campaign of education that physicians throughout the State be supplied with warning slips to be sent to all the families in their respective practices, which slips shall bear the endorsement of approval of the local Board of Health and the local County Medical Society and which slips shall urge the administration by the family physician of toxin antitoxin to all children up to ten years of age.'

I move the adoption of this recommendation.

Motion seconded and carried.

"Your Reference Committee commends the report of the committee and recommends its adoption as a whole." Motion seconded and carried.

# 57. TREASURER'S AND TRUSTEES' REPORTS

Dr. Trembley, of Franklin: The report of the Treasurer has been reviewed by your Reference Committee, who desire to commend the Treasurer upon his excellent and concise report and to suggest that it be accepted and approved by the House of Delegates.

In reviewing the report of the Trustees, your Reference

Committee wishes to commend them for their watchful economy where expenditures were not justifiable, and their wise additional appropriations where the work of the committees would have been handicapped by the amount assigned in the budget.

I move the adoption of the report.

Motion seconded and carried.

The Speaker: Are there any other committees ready to report?

## 58. ARTICLES ON ECONOMICS IN THE JOURNAL

Dr. Krieger, of Dutchess-Putnam: Reference Com-

mittee A, presented the following resolution:

RESOLVED, That the New York Journal of Medicine devote more space to economic matters in preference to

scientific articles.

We will say as to that, that the Journal has given all the space it has been asked for, for economic articles. The Journal has repeatedly asked for articles on economics, but has not had any response, and that ten per cent of articles in the Journal have been on economic matters.

We recommend that this resolution be referred to the

Editor-in-Chief of the Journal.

Motion seconded and carried.

# 59. LIST OF PHYSICIAN BENEFICIARIES OF WORKMEN'S COMPENSATION

Resolven, That the Medical Society of the State of New York, through its Secretary, obtain an annual report, if possible, of the medical beneficiaries under the compensation law.

The committee does not approve this resolution, and I

move that it be not adopted.

Motion seconded.

Dr. Rooney, of Albany: I rise to a point of information. As some of the delegates are not familiar with the exact tenor of the resolution, I would request the pro-

poser to state its purpose.

Dr. Bonnar, of Eric. In this resolution, which was passed by a large majority of the Eric County Society lie Secretary of the State Medical Society is requested to institute means if possible by which we can, in a measure, determine where this reputed \$20,000,000 is spent by the insurance societies, or the State, in behalf of the Workmen's Compensation Service. Where did this \$20,000,000 go? Who were the beneficiaries of this \$20,000,000? We want the attitude of this House of Delegates on this all-important financial measure. It is an economic measure, because if you take the \$20,000,000 and divide it up amongst the 12,000 doctors of this Society, it would go a long way to eliminate any hardships, and aid them materially.

The Secretary: It is absolutely impossible for the Secretary's office to compel the thousands of people that are receiving compensation to give this information. There is no machinery through which it could be handled. There is no way by which it may be obtained. The resolution says, if possible but I say it is impossible.

lution says, if possible, but I say it is impossible.

Dr. Rooney, of Albany: All this money spent is a mater of public record. Any physician can get it; I can see no reason for placing the additional burden on our Secretary.

Dr. Bonnar: I just want to say that the information given by Dr. Rooney is exactly what we want, and that the information ought to be brought home.

Motion made and duly seconded that this resolution

be not adopted. Carried.

8.)

## 60. Officers Opposing Official Actions

# Dr Krieger: I have another resolution. (See Section

RESOLVED. That any officer or member of a committee of the Medical Society of the State of New York, or any officer or member of a committee of a county medical society shall first resign his official position before oppos-

ing any resolution or measure which the State Society or his county medical society has adopted.

The committee does not approve of this resolution.

I move that it be not adopted.

Dr. Rooney moved that the recommendation on this resolution, and the resolution itself, be tabled (See Section 78)

Motion seconded, voted upon and carried.

#### 61. PERSONNEL OF COMMITTEE ON MEDICAL ECONOMICS

Dr. Krieger: Resolved, That the activities of members of the Committee on Medical Economies of the Medical Society of the State of New York, as shown by opposition to the bill for free choice of physician in compensation cases and in other matters affecting the economic side of medical practice calls for an entire new personnel and shall not be chosen from physicians who are connected with industrial plants. (Section 7.)

The committee does not approve of this resolution, I

move that it be not adopted. Motion seconded.

The Speaker: The motion before you is not to adopt that resolution.

Dr. Leitner, of Rockland: The committee would like to reconsider this whole question, and we will make another report and bring it before the House.

Motion seconded.

The Speaker: The motion before the House, which was made and seconded is, that this resolution be referred back to the committee for reconsideration.

On vote the motion was carried.

#### 62. FREE CHOICE OF PHYSICIAN

Dr. Krieger: Whereas, under the terms and provisions of the Workmen's Compensation Law, the injured employee is deprived of a right to select his own physician and

WHEREAS, this situation likewise obtains in cases coming within the jurisdiction of the State Insurance Fund, Now, be it

Resolved, that the New York County Delegation request the Medical Society of the State of New York through its proper committee to confer with the Commissioner of Labor with a view to enlisting the support of said Commissioner of Labor in cases coming under the Jurisdiction of the State Insurance Fund, to permit the injured employee to select in the first instance a physician of his own choice. (See Section 21.)

The committee recommends the adoption of the suggestion that the action taken by the House of Delegates last year on the free choice of physician be reconsidered.

I move the adoption of this recommendation. Motion seconded.

The Speaker: The motion before the House now is to reconsider the action of the House of Delegates taken a year ago, with reference to the free choice of physicians.

Dr. Rooney, of Albany: It seems to me that we are dealing with a matter of great importance; we are dealing with a situation that does not alone exist in New York City, one which is present in every state of the Union, that is working under this law.

You gentlemen must know, and I am sure you do know, that what legislation you enact in this House, and that as a result of the legislation enacted here, the changes that are made in the organic law of the State, of which we are all citizens, are embodied in the body of the law of practically every state of the Union. You can expect the repeal, within five years, of any law that is not enacted as a law in this State.

Now, this controversal matter, has been agitated here year in and year out, for a great many years, and this House has gone on record in opposition to the principles the chairman of your reference committee which recommends that we reconsider statements that have been made year after year for six or seven years.

If you do it, gentlemen, you will inculpate your selves. If you do it, you do in effect justify every one of these interests that have been organized, many of the larger interests, against us. I know, because I have seen this movement increase. Some six years ago I sat in a committee of this Society, which was asked for by the then Commissioner of the Workmen's Compensation Bureau, Mr. Sayer. Mr. Sayer endeavored to his utmost to have three representatives of this Society on that Committee, and when this was learned, what did they do, made Mr. Sayer head of the Liability Agency in New York City.

Now, let us not be sentimental about it. We are not going to get it next year or the year after, or the year after that, because we have against us bodies whose interest this will not serve; but, shall we fail? Shall we fail in a matter of principle, and accept the position

of defeat?

Dr. Sherwood of Niagara: In addition to what Dr. Rooney has pointed out to this body, please bear in mind that no doubt within the not distant future, we will have some form of industrial health insurance

This bodes ill for the general practitioner.

The reason this body has been in favor of this idea of freedom of choice, is in behalf of the general man trying to make his way in the general practice of medicine. Our County Society, however, went into that, into this matter of choice of physicians, in compensation cases, not thinking that those so active in its behalf would make the progress that they made at the last session of the Legislature. They were surprised, and those members of the Associated Industries, in Niagara Falls, were very apprehensive lest this bill become a law. However, the answer of this body, and of those counties which endorsed this move, have been impressive to those who have been trying to treat with members of the Associated Industries, to protect themselves.

The principle of free choice is very fine, and hardly a physician will disagree with the principle, but the application of that principle is the stumbling block, and until the State Society devises some means by which those who pay the bills are protected, they are bound to suffer, as every man of practical experience knows.

I, for one, would like to know what the Medical Society of the State of New York has to offer to protect those who are paying the bill.

Dr. Sadlier, of Dutchess-Putnam: As the introducer of this resolution, and as one who voted last year for the free choice of insurance in industrial places, I should like to say a word in reference to the resolution before

Industrial Compensation Insurance is for surgical work, not medical, and furthermore, it is a specialized branch of surgical work to a very criticizable degree, getting more and more so every day. It involves a very vast responsibility. I have seen before us, day by day, in our individual practice, the question of lacerated hands and compound fractures, and the various forms of injury in the industries. I ask you, would you have an injured man go to a medical man, or would you

have him go to a surgeon?

Furthermore, we are placing the Medical Society of the State of New York in a rather peculiar position. We are asking for something that the employee or at least the Department of Labor, does not seem to be asking for. Now, I understand, I was not there, but I understand at the hearing on this amendment, this last winter in Albany, that labor did not raise its voice in favor of this amendment. Are we not being placed in a rather false or selfish position, asking for something that the employees want? I hope there will be a general rediscussion of this. It is an important question, and ought to be decided.

Dr. Leone of Eric: I am opposed to that resolution.

I might state in the beginning that I was the one that appeared in behalf of this bill last winter, and it is very much the fact that labor was not represented, and there were very few of us there. There was a representative of the State Industry there, and he brought there all he could get, perhaps in behalf of the opposition. My small committee financed its own activities, had to take care of their own practices but naturally we were limited by time and circumstances, to go up and down the State, to bring the labor people to the Council at Albany, but I have assurances from a great many of them that they are heartily in favor of our bill, so don't let anyone think that because last year there were a few of us there, that that does not mean that there is no one for the bill.

I want you to know that there is a good deal of sentiment throughout the State in favor of the workmen, and I am pretty sure that this proposition is coming to the fore again, perhaps next year.

Dr. Kopetzky of New York: The County from which I am a delegate is on record and has stood for the free choice of physicians by the injured workman, and we would deprecate any action by the House of Delegates here, of vitiating that stand. The accidents that terminate a notification, do not seem to be lessened, when they go to an Industrial Agency, as they do now in New York, to the Myer Wolf Agency, to adjust the same, because of the inexperienced men who handle them individually. I think that the statements of Dr. Sadlier are an indictment of the profession, and I do not think he wants it understood as such. This body is here to legislate on the assumption that we are dealing with honest, competent practitioners.

I think Dr. Rooney has hit the key note in this matter. The steps abrogating the right which we claim of the free choice of the injured, to seek his physician would be a step backward for this Society, and I hope that

that resolution will not prevail.

Dr. Thomson of Wyoming: I want to say that I entirely agree with Dr. Sadlier. We are not taking into consideration the public. The public must be protected to a certain extent. An injured man sometimes does not know what he should do about a physician. He does not know that one man is better for doing certain work than another man. Take myself, for instance. I cannot treat a fracture as well as another man in my own county, because he knows better how to handle that.

Dr. Cottis of Chautauqua: They work both ways. We assume that all the members of our profession are honest and qualified men. If I understand it, the men who are proposing the continuance of our stand on the free choice, are doing it largely on the theory that any man who has the choice, is naturally a crook.

There is no question, that there is a difference in the qualifications of medical men, to do certain classes of work. You wouldn't go on record in telling the public that if they had to have a cardiac operation that they are crazy to go to any man with an M.D. after his name. We also recognize the fact that there are men who are not qualified to consider cases like that, or to consider a traumatic surgery. It is true that these industrial organizations, like the Wolf agency, recognize this. We ought not to stand for it, but we are not going to get rid of those who do, and we are standing for that, if they stand for that, that the workmen should have no protection whatever.

It seems to me that we ought to recognize both these things, that the present Industrial Commission is bad, and it is a question of whether the Medical Fraternity and the public are men free and equal.

I would like to see Dr. Sadlier's resolution prevail, but I would like to clear the air, and get this thing out of the way. I mean, this extreme attitude and start in the proper way, that we should have a free choice among qualified men, that we should work out

some system by which the community should have a list of names that are perhaps recommended by the County Society as being men who have the proper

County Society as being men win have the proper training to take care of surgical cases.

Dr. Ferber of New York spoke along the same lines as did Dr. Hoywood, of the Bronx; Dr. Colic, of New York, and Dr. Woodruff, of Erie.

The Speaker: We will now take a vote on this control of the speaker of the thouse is that the proposition. The question before this House is, that the House of Delegates reconsider its action of a year ago on the free choice of a physician in compensation cases. The action a year ago was that they approved the free choice of physicians Now, Dr. Sadlier's resolution is that we reconsider that.

The motion was seconded, and on vote it was de-

feated. Dr. Kopetsky of New York: I now move the adoption

of the original resolution.

The Speaker: You heard the original resolution read.

Motion seconded and carried.

Dr. Rooney of Albany: I move that a Special Committee be appointed composed of members who have declared themselves in favor of free choice of physicians, in Compensation Cases, for the purpose of unifying all of the interests.

Motion seconded.

Amendment made that it be with authority to make

necessary provision for counsel.

Amendment seconded and carried.

## 63. SUPPORT OF PUBLIC HEALTH MEASURES

Dr. Krieger: The committee has again taken up the following resolution. (See Section 40.)

WHEREAS, Governmental officials and legislative bodies concerned with the protection of the public health are often petitioned to abolish existing health and welfare

protective measures, and

WHEREAS, The medical profession is frequently represented as being opposed to these destructive procedures from ulterior motives; Therefore, be it
RESOLVED, That the Medical Society of the State of
New York, through its appropriate State and County
Committee concerned with public health, public relations
and legical test constructions. and legislative matters, use all legitimate efforts to arouse the interest of official and unofficial agencies concerned with the maintenance of health, to the end that they will obtain, by petition or otherwise, adequate appropriate support by the general public to counteract petitions now known to be in circulation for the purpose of creating sentiment favoring the repeal of such constructive health measures as vaccination against smallpox, immunization against diphtheria, and the like.

I move the adoption of this resolution.

Motion seconded and carried.

#### 64. COMMITTEE ON MEDICAL RESEARCH

Dr. Farmer: Your Reference Committee on the Reports of the Committees on Medical Research and Periodic Health Examinations has reviewed the report of the Committee on Medical Research (Journal, May 1, page 523) and recommends that the committee be commended for its action in opposing the Vaughn Assembly Bill Int. No. 157 in the State Legislature and the Bill HR 1884 in Congress, and that the chairman and members of the Committee on Medical Research be thanked for their services.

I move the adoption of the report. Motion seconded and carried.

#### 65. COMMITTEE ON PERIODIC HEALTH EXAMINATIONS

Your Reference Committee has carefully reviewed the report of the Committee on Periodic Health Examinations. The report is extensive and widespread in its scope, and indicates that the Committee on Periodic Health Examinations has been very active during the past year. In its report it envisions a ten-year program.

While, undoubtedly, this is in conformity with the instructions of the House of Delegates in creating the Special Committee on Periodic Health Examinations last year, still your Reference Committee does not believe that the State Medical Society at this time should adopt or ap-prove such a program but rather should instruct the Special Committee on Periodic Health Examinations to make further studies in order to report more concretely just what such a ten-year program would comprise, the cost of such a program and to what extent the State Medical Society would be involved.

The Committee on Periodic Health Examinations presents two resolutions in its report. One is as follows:

Be It Resolven, That the Medical Society of the State
of New York hereby recognize its duty and privileges in

the premises as follows:

The Society should take a leading part in the education of the public on the subject of periodic health ex-amination, cooperating with responsible organizations of a public, semi-public or private character, working toward the same end.

The Reference Committee recommends the approval of

this resolution.

I move its adoption. Motion seconded and carried.

In the report of this resolution is discussed in two parts, A. and B. Under the relation of the State Medical So-A and B. Under A the relation of th State Medical Society to a large number of other organizations is taken up. Your Reference Committee believes that the State Medical Society should take the leading part in a cam-paign for periodic health examinations. Your Reference Committee further believes that the Committee on Periodic Health Examinations should work with the standing Committee on Public Relations in evolving a plan of cooperation with other organizations in a campaign for Periodic Health Examinations. Under B: The committee recommends that there shall be prepared by the Society a plan of procedure for health examination campaigns to be conducted by the local committee or city medical societies. Your Reference Committee recommends that the Special Committee on Periodic Health Examinations prepare a model plan of procedure for health examination campaigns for use of county medical societies.

I move the adoption of this part of the report.

Seconded and carried.

The second resolution is as follows:

"BE IT RESOLVED, That the Society undertake to inform its members in so far as possible, as to the best methods of conducting health examinations for men, women and children under the various conditions of life, employment and other circumstances, so that they may receive the greatest possible benefit from the procedure. Furthermore,

Be IT RESOLVED, That the Society investigate the health examination procedures now carried on by various commercial organizations, industries, associations and the like, with reference to the character and efficiency of the examination, the benefit to the examinee, the compensation to the medical examiner, and general effect of this growing practice upon the welfare of the public and the medical profession; and that the Society deduce from this investigation a set of principles of procedure with reference to the economic aspects of the health examination."

Regarding the first part of this resolution your Refer-

ence Committee would state that the instruction to the medical profession on the technique of making a periodic medical profession on the technique of making a periodic health examination properly, has been and still is offered to county societies by this State Society under the direction of the Committee on Public Health and Medical Education in cooperation with the Special Committee on Periodic Health Examinations. Regarding the second part of the resolution your Reference Committee, while aware of the apparent need for the investigation of health examination procedures by various commercial organizations, etc., nevertheless feels that the Special Committee

Examinations should obtain more regard and report the same to the Committee which could then authortion after having obtained advice of matter. Regarding the relation of ninations to industry and employees it t such matters be left to the Commitnomics subject to the aid and advice umittee on Periodic Health Examinaecommendation is made regarding the ation dealing with the examination of Your Reference Committee believes that as to the Committee on Legislation.

on Periodic Health Examinations redures for the purposes of: "A. Interesteties in periodic health examinations. ussion in the county society of the entire ning a preliminary allocation or designans willing to interest themselves in periminations, and to hold themselves out as multee approves Procedure No. 1: "The e health examination shall be outlined to reieties." Your Reference Committee aplure No. 2. "Endorsement of the value and ciety." Your Reference Committee approves o 3. "News items in all local papers cover'c."

crence Committee does not approve Procedure h reads as follows: "Carefully prepared, paid nts to appear in local papers, expounding calth examination. Advertisements to appear orization of county medical society (and State ) and to be paid for and subscribed to by those ty society members who volunteer to do so." ur belief that this matter should be left to edical societies and that no advertisement should nder the authorization of the State Committee the approval of the House of Delegates, Council utive Committee.

e that this recommendation be not adopted. ded and carried.

Reference Committee commends the Special ttee on Periodic Health Examinations for organis public meeting to be held immediately after the ssion of this year's annual meeting, believing that a meeting will arouse enthusiasm in popularizing ic health examinations.

have that the report of this committee be adopted whole.

conded and carried.

### 66. Prescriptions for Alcohol

he Secretary: The following resolution has been ded in by the Warren County Society:

The National Prohibition Act concedes to physicians legal right to prescribe and use alcoholic liquors when ysical examination shows them to be necessary in the re of the sick and

WHEREAS, The regulations of the Prohibition Act and repartment regarding such use and prescribing are detrirental to the sick and obnoxious to members of the medi-

al profession for the following reasons:

First: Because they arbitrarily limit the amount of alcohol a physician may prescribe for a sick person without taking into consideration the kind of illness from which the person suffers or any other circumstance which a physician considers in determining what dosage is required and

Second: Because they require physicians to file with the Prohibition Department the names of patients for whom alcoholic liquors are prescribed and the names of the dis-eases from which those patients are suffering thus forcing physicians to violate one of the fundamental principles of their profession and disclose facts about their pa-

tients which are sacredly confidential and which should not be revealed by the physician under any circumstances.

BE IT RESOLVED, That the Medical Society of the County of Warren takes this occasion to register a vigorous protest against that provision of the act which dictates to our profession what dosage of this medicinal agent we may use in caring for the sick and our Society aiso

PROTESTS against that section of the regulations which forces us to betray the confidential communications of our sick patients and to reveal the nature of their dis-

eases and

BE IT FURTHER RESOLVED that this protest be spread upon our minutes and that copies he sent to our representatives in the state and national legislature and to the local newspapers and that our delegates to the State Medical Meeting be instructed to ask the cooperation of the State and National Medical Societies for the elimination of these intolerable conditions. (See also Section 9; for action, see Section 76.)

The Speaker: Referred to Committee on New Business B.

67. STERILIZATION OF THE UNFIT

Dr. Townsend, of New York: Your Reference Committee on New Business C has the honor to submit this report as the result of their deliberations.

1. We recommend the rejection of the resolution on "Sterilization of the Unfit" since the definition of "The Unfit" is so vague as to permit a large source of error. (See Section 10.)

We move the adoption of this resolution. Motion sec-

onded and carried.

68. CHARGES TO INDUSTRIAL PATAENTS IN FREE WARDS

2. We recommend the adoption of the resolution to revise the Municipal Charter of the City of New York to permit attending physicians to receive fees for medical and surgical services rendered to industrial patients in municipal hospitals.

We move the adoption of this resolution. Motion sec-

onded and carried. (See Section 20.)

## 69. PAY CLINICS

3. We recommend the adoption of the resolution reg istering the protest of the delegates from New York County against the maintenance of pay clinics as now operated under the provisions of the Dispensary Law of the State of New York.

We move the adoption of this resolution. Motion sec-

onded, and carried. (See Section 17.)

# 70. Governor's Special Health Commission

4. Your committee recommends the adoption of the resolution expressing approval of the action of the Governor of the State in creating a special Health Commission and its recommendation in preserving strategic re-lationship between physician and patient rather than impersonal relationship between State and patient. (See Section 13.)

We move the adoption of this resolution. Motion sec-

onded and carried.

# 71. COMMERCIALIZATION OF MEDICAL PRACTICE

5. We recommend the adoption of the resolution criticizing such physicians who commercialize the practice of their profession by entering the employ of chain stores or department stores in a professional capacity except when in the employ of said store in the care of its employees. (See Section 15.)

We move the adoption of this resolution. Motion sec-

onded and carried.

# 72. Physicians' Cards in Daily Newspapers

6. We recommend the rejection of the resolution concerning the publication of medical notices of individual

physicians, believing that this is a matter for adjustment by the county societies as varying conditions present themselves, (See Section 38.)

I move the adoption of this recommendation.

Motion lost.

The Speaker: Will Dr. Townsend read the original

Dr. Townsend: WHEREAS, the Bronx County Medical Society feels that the publications in the foreign press of the City of New York of medical notices of individual physicians is contrary to the true spirit of medical ethics, and

Whereas, such publication has heretofore been con-doned by the Medical Society of the State of New York.

Therefore, be it

RESOLVED, that the Medical Society of the State of New York express its disapproval of such publications and consider it contrary to the practices and principles of ethics of the medical profession.

It was moved that this original resolution be adopted.

Seconded and carried.

# 73. New York Academy of Medicine's Report on Unethical Practices

7. We recommend the rejection of the resolution concerning the unpleasant publicity resulting from the releases of the annual report of the New York Academy of Medicine because of unsupported statements contained in the resolution. (See Section 39.)

I move the adoption of this recommendation.

Seconded and carried.

Motion to adjourn until 7:45 P. M. made, seconded and carried.

The Speaker: I will call on Dr. Kosmak, of New York, Chairman of Reference Committee B on New Business.

#### 74. QUALIFICATIONS FOR PUBLIC HEALTH POSITIONS

Dr. Kosmak: I have a number of resolutions, which this committee has had under consideration. This is the first set of resolutions. (See Section 11.)

WHEREAS, in the early days of health work health officers were practicing physicians or, sometimes, laymen,

WHEREAS, today special training leading to degrees in

WHEREAS, today special training leading to degrees in public health is available; now, therefore, be it RESOLVED. That the Medical Society of the State of New York, through its State and County Committees on Public Health and Public Relations, advise the public of the need of special training and aptitude for public health work, and be it further RESOLVED. That these committees inform appointing in-

dividuals and boards that specially qualified personnel should be appointed to positions involving responsibility

for community health; be it further

RESOLVED, That nothing in this resolution is intended to displace or disparage present officers who, through long experience, have acquired much of the information which is now being given by formal instruction, but that the only intent of the resolution is to provide for filling vacancies and newly created positions in health work.

The committee universally approved this set of resolu-

tions, I move their adoption.

Motion seconded and carried.

## 75. PAY OF PHYSICIANS IN PUBLIC EMPLOY

Dr. Kosmak: WHEREAS, employed physicians in the State of New York are paid on the average less than \$500 per hour; now, be it

RESOLVED, that the New York County Delegation expresses the conviction and opinion that employed physiclars should be paid a minimum fee of \$5.00 per hour. (See Section 22.)

The committee disapproves of this resolution.

I move that it be not adopted.

Seconded and carried.

#### 76. Prescriptions for Alcohol and Narcotics

Dr. Kosmak: WHEREAS. The confessions of the penitent to his priest, the communications of the client to his counsel, and the confidences of the patient to his physician, have been held inviolate from remote ages and have been jealously guarded by the courts, and

WHEREAS, the regulations of the Volstead Act for the enforcement of the 18th Amendment and the provisions of the Harrison Act require the physicians to state the diagnosis of the disease or ailment of the patient on the

stub of every prescription they write for narcotics, and WHEREAS, The stubs of all prescriptions for alcohol must be surrendered to Prohibition Commissioners for inspection by them and their clerks and all prescriptions for narcotics are open to inspection by Federal agents,

now, therefore,

BE IT RESOLVED. That the Medical Society of the State of New York hereby voices its protest against those portions of the prohibition and narcotic laws which deprive the citizen of his age-old right to privacy regarding his diseases and ailments, which compel the physician to betray the confidential communications of his patient, BE IT FURTHER RESOLVED, That the Delegates of the

Medical Society of the State of New York to the American Medical Association be, and hereby are, instructed to present the above resolution to the House of Delegates of the American Medical Association for action at its

next meeting in Detroit. (See Section 9.)
I move the adoption of these resolutions.

Motion seconded and carried unanimously. Dr. Kosmak: I have another set of resolutions of a similar character introduced by the County of Warren. (See Section 66)

WHEREAS. The National Prohibition Act concedes to physicians the legal right to prescribe and use alcoholic liquors when physical examination shows them to be necessary in the care of the sick, and

WHEREAS, The regulations of the Prohibition Act and Department regarding such use and prescribing are detrimental to the sick and obnoxious to members of the medical profession for the following reasons:

First: Because they arbitrarily limit the amount of alcohol a physician may prescribe for a sick person without taking ind of illness from which the · · zircumstance which a physicia . what dosage is required and

Second: Because they require physicians to file with the Prohibition Department the names of patients for whom alcoholic liquors are prescribed and the names of the diseases from which those patients are suffering thus forcing physicians to violate one of the fundamental principles of their profession and disclose facts about their patients which are sacredly confidential and which should not be revealed by the physician under any circumstances. Therefore,

BE IT RESOLVED, That the Medical Society of the County of Warren takes this occasion to register a vigorous protest against that provision of the Act which dictates to our profession that dosage of this medicinal agent

we may use in caring for the sick and our Society also PROTESTS against that section of the regulations which forces us to betray the confidential communications of our sick patients and to reveal the nature of their diseases and

BE IT FURTHER RESOLVED. That this protest be spread upon our minutes and that copies be sent to our representatives in the state and national legislature and to the local newspapers and that our delegates to the State Medical Meeting be instructed to ask the cooperation of the State and National Medical Societies for the elimination of these intolerable conditions.

I move the adoption of this resolution

Motion seconded and carried.

# 77. PRACTICE OF MEDICINE BY CORPORATIONS

Dr. Kosmak: WHEREAS, there have recently sprung up a number of organized groups practicing medicine under

an incorporate name, be it

RESOLVED, that the House of Delegates of the Medical Society of the State of New York bring a test case before the higher courts to test the legality of these corporations practicing medicine under the laws of the State of New York. (See Section 16.)

After a conference between our committee and the endorser of this resolution, he has agreed to withdraw the

same as a matter of expediency.

The Speaker: It will so be recorded in the minutes. The Speaker: Are there any committees that have anything further to report?

# 78. OFFICERS OPPOSING OFFICIAL ACTION

Dr. Krieger: The committee has reconsidered the resolution which was referred back and we disapprove of it as worded. I would ask you that if the person introducing this resolution would make it specific so that the committee could understand it, we would be very glad to reconsider it

The Speaker: Then the committee wants more information?

Dr. Krieger: Yes.

The Speaker: Please read the resolution.
Dr. Krieger: Resolved, That any officer or member of a committee of the Medical Society of the State of New York, or any officer or member of a committee of a county medical society shall first resign his official position before opposing any resolution or measure, which the State Society or his County Medical Society has adopted.

No action taken on this resolution.

# 79. COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

Dr. Howland: Your Reference Committee on the Report of the Committee on Public Health and Medical Education heartily endorses the work of the committee on their Graduate Education program. (See Journal, May 1, page 523.)

We endorse the recommendation that the charging of a registration fee be indefinitely postponed, and the grouping of counties be encouraged as far as possible.

We congratulate the committee on the new courses offered, and urge their acceptance by the county societies.

We endorse the plan for the extension of graduate teaching by giving over a whole day for four to six lectures, and second, the extension of more intensive clinical teaching to small groups simultaneously with the weekly lectures.

The committee feels that the Committee on Public Health and Medical Education know better which courses are best adapted to any given county. We offer the suggestion that county societies planning their courses for the coming season consult early the chairman of the Public Health and Medical Education Committee for in-

formation and advice.

We note that the Public Health and Medical Education Committee have been very active in public health activities during the past year, that it met with twelve other committees for discussion of problems of great importance to our Society and the public at large; all this we heartily endorse, and we wish to congratulate the Society on the excellent work which has been done by this Committee, as is evidenced by its report and the results so far obtained, and we wish to call special attention to the remarkable work done by its Chairman Dr. Thomas P. Farmer, and to express the hope that he will be continued in this important position, until he may carry to completion the work so ably outlined.

I move the adoption of this report.

Motion seconded and carried.

Dr. Howland: The Reference Committee also has a supplementary report to consider here.

The committee held a meeting in New York City on April 17th, at which time the subject of cancer as a public health problem and especially the relation of the work of the American Society for the Control of Cancer in the State of New York to this problem was discussed.

The following resolutions were adopted:

RESOLVED. That since the cause of cancer is not definitely known and its treatment definitely settled, the Committee on Public Health and Medical Education feels that information to the public about cancer should be in the hands of medical men whose minds are receptive to any suggestion, treatment, thought or plan of action concerning this disease which will stand scientific investigation, and that this committee support all efforts toward such scientific investigation.

RESOLVED, That the Committee on Public Health and Medical Education incorporate among its postgraduate

courses lectures on cancer.

RESOLVED, That it is the opinion of this committee that the work of Dr. Swan, as director of the New York State Committee of the American Society for the Control of Cancer has been a benefit to the people of the State. The committee recommends that the future direction of this work be continued in the hands of a regular licensed physician who is a member of the Medical Society of the State of New York.

The committee also approved of a plan for publication in the Journal of the State Society of short articles on "How Physicians Can Practice Medicine in Their Regular Routine Work."

I move the adoption of this report. Motion seconded and carried.

# 80. COMMITTEE ON POLLUTION OF WATERWAYS

Dr. Stetten, of New York: Reference Committee on the Report of the Committee on the Pollution of the New York Waterways, begs to report as follows (Journal, June 1, page 664):

Your Reference Committee compliments the Committee on the Pollution of Waterways upon its careful analysis of the problem, and heartily approves the recom-

1. That the Medical Society of the State of New York approves of the desire and plan of the State Department of Health to secure for all municipalities supplies of water from sources other than rivers.

2. That the Medical Society of the State of New York commends the activities of the State Department of Health aiming ultimately to secure universal treatment

for all sewage deposited in the rivers.

3. That the Medical Society of the State of New York endeavor, through its membership, to acquaint the public with the facts above detailed and secure as far as is possible enthusiastic support of the principles "No river water for domestic purposes" and "No untreated sewage for the Mohawk and Hudson Rivers.'

I move the adoption of this report. Motion seconded and carried.

# 81. Committee on Nursing

The Speaker: Are there any other committees ready to report?

Dr. Cunniffe: Your Reference Committee on the Reports of the Committee to Study the Nurse Problem

and on Physical Therapy.

The statistics showing the status of the nurse in the different parts of the State contained in this report is noted, also the new standards for admission to Training School which require two years of High School in 1930, three years in 1931 and four years in 1932. These requirements are now a law having been enacted by the last Legislature. (Journal, June 1, page 668.)

The statement regarding the non-enforcement of the Nurse Registry Law and the request of this Committee

for a favorable action by the House of Delegates in the form of a request to the Department of Education to stimulate the License Bureau to the observance of this law is approved and, therefore, we suggest that the House of Delegates forward this request to the Department of Education. I move its adoption. Sec-

onded and carried.

The Committee's recommendations that the student entering a school of nursing should be at least 18 years of age, should present a certificate of complete health examination from a physician known to the school, that she have character endorsements from two reputable persons, one of whom should be a physician, that no hospital should conduct a training school of nursing where the daily average of patients is less than twenty with affiliations or less than fifty without affiliations.

I move its adoption, Motion seconded and carried.

The recommendation that she be a native or citizen of the United States, is considered unwise and un-American, and is therefore disapproved, and I so move.

Motion seconded and carried

Dr. Cumiffe: The Committee approves the recommendations regarding Group Nursing in hospitals, part-time or hourly nursing in homes, and the liberal support of visiting nursing organizations, only when properly supervised by medical authority, and we recommend its adoption.

I move its adoption.

Motion seconded and carried.

#### 82. COMMITTEE ON PHYSICAL THERAPY

Dr. Cunniffe: Your Reference Committee commends the Committee on Physical Therapy especially for its activities in sending information regarding the status, scope and limitations of physical therapy to the different county societies, hospitals and interested physicians. (See Journal, May 1, page 521.)

The report on the inadequate physical therapy teaching in medical colleges of the State of New York is noted and this committee feels that the Medical Society of the State of New York should recommend that or the State of New York should recommend that more instructions be given to the undergraduates in the different medical schools of the State, also they should suggest the introduction of a post-graduate course in physical therapy for which course Physicians only would be eligible, it is felt that in this way more physicians will be induced to study physical therapy, thereby increasing their efficiency and decreasing the field of activity for the non-medical physiotherapist. I move the adoption of this recommendation.

Seconded and carried,

The committee's action in endeavoring to stimulate interest in physical therapy, in recommending the appointment of special committees on physical therapy in the different county societies, in inviting the County Committees to attend the stated monthly regional meetings, also the work of the Chairman in addressing the different county societies and for arranging a program for the State Society Meeting in Rochester, is noted and commended.

and commenced.

The committee's report reads as follows: A peculiar situation was created by the abusinshment of the Medical Practice Act, to practice physiotherapy to the practice physiotherapy to the constraint of this constraint of the constra

the carrying out of this supervision or for the revocation of the license for due cause.

It is recommended that this situation be called to the attention of the State Legislative Committee with instructions to introduce necessary legislation to correct

it,

The report of the committee on the matter of physical therapy in industrial work is so incomplete that no recommendations can be made. It is suggested, however, that this matter be investigated still further and a more complete report of the situation be presented at the next annual meeting.

I move the adoption of this report Motion seconded and carried.

#### 83. COLLECTION AGENCIES

Dr. Goodrich: The report of the special committee to consider the resolutions of the Medical Society of the County of Erie, of April 23, 1930, and the report of the Special Committee of the Committee on Medical Economics:

Your committee, appointed by the President to consider the resolutions from the Medical Society of the County of Erie, having considered:

(a) the Resolutions, (b) the report of the Special Committee from the Committee on Economics,

(c) a second communication from Erie County Society submitted by the Secretary,

(d) the complete report of the Committee on Eco-

nomics, and (e) the form of contract issued by the Knicker-

bocker Adjustment Service Company; make the following report.

1. While absolving the said Adjustment Service Company from any intent to deceive, there are certain ambiguities in the wording of their contract which might readily mislead. Because of this we believe that certain of the complaints set forth in the Erie County

Society's resolutions are well founded.

2. We recommend that the House of Delegates establish by resolution, the policy of accepting no advertisements of collection agencies unless such agencies are formally certified by the Society.

3. We recommend the official deletion from the records of this Society paragraphs Nos. 5, 6, 7, 8 and 9 of the Report of the Committee on Medical Economics as printed on pages 33 and 34 of the Annual Reports.

I move the adoption of this report. Motion seconded and carried.

#### 84. COMMITTEE ON MEDICAL ECONOMICS

Dr. Stetten: Your Reference Committee on the Report of the Committee on Medical Economics has carefully considered the committee's report. (Journal, May 1, page 527.)

In regard to fees paid to physicians for insurance work, your Reference Committee concurs in the Committee's opinion that fees for health and accident insurance examinations should be the same as fees for life insur-

ance examinations.

In regard to the Knickerbocker Adjustment Service Company in New York, your Reference Committee deems the inclusion of this discussion inadvisable in the committee's report, and recommends the deletion of the entire matter from the records of the Society.

Your Reference Committee also believes that the paragraph containing personal reference to Dr. Knicker-bocker should also be deleted from the report.

Your Reference Committee concurs in the suggestion of the Committee on Medical Economics that full-time personnel should be employed by the State Society to combat the evils tending toward the economic detriment of the practitioner of medicine,

I move the adoption of this report.

Motion seconded and carried.

#### 85. REIMBURSEMENT FOR EXPENSES

Dr. Goodrich: The Reference Committee on the Address of the President will continue its report as follows:
In regard to re-referred articles, the committee favors the reimbursement of hotel and necessary expenses of the members traveling on Society's business, and urges the adoption thereof, and recommends that this matter be re-

ferred to the Executive Committee for consideration and recommendation to the Board of Trustees. I move the adoption of this report.

Motion seconded and carried. (See Sections 30 and

# 86. Bond of Those Appealing to Censors

In regard to the recommendation concerning Censors (see Section 28), we recommend that there be added to Section 3, Chap. 10 of the By-Laws, the following words:

"The appellant must also state if he desires to be present in person or by counsel. In the event that the appellant shall so declare, he must file with the notice of appeal a bond in the sum of Five Hundred Dollars to cover the costs of said appeal. In the event that the appellant fails to appear, either in person or by counsel, after making the aforesaid declaration, he shall forfeit to the State Society, such share of said bond as represents necessary expenditures incident to convene the Board of Censors on said appeal."

Also add to Sec. 7, Chap. IX.

"The Appellant must also state if he desires to be present in person or by counsel."

I move the adoption of this report.

The Secretary then moved on a point of order, stating that it is an amendment to the Constitution, and has to lie over until next year.

The Speaker: The report of the committee will have

to be accepted or rejected.

The Secretary: This House cannot accept a recommendation on an amendment. The committee can recommend that an amendment be placed before the House and laid over, but they cannot recommend its acceptance.

Motion made to adopt the report of the committee with the exception of the amendment to the By-Laws.

Motion seconded and carried.

Dr. Rooney: I hereby give notice of a proposed amendment to the By-Laws as suggested by the chairman of the committee. It will lie over until next year.

# 87. Publications and Medical Publicity

Dr. Goodrich: In regard to the recommendations of the President concerning a Committee on Publicity, we would first offer his peroration as a preamble (see Journal. May 1, page 499):

"Lay people are more medicine conscious in these years since the War. We are only doing a small part in guiding their education or reading, and are leaving this to organizations who have ideal at times, I fear, higher than ours, as exhibited by their efforts, while we supinely stand aside and let them pull or push us about."

We recommend:

First: The abolition of the present Publication Com-

mittee of the Executive Committee.

Second: The establishment of a new Standing Committee of five in accordance with the President's recommendation, to be called the Committee on Publication and Publicity. This change of name is suggested for the sake of clarity. The establishment of this committee would make necessary its addition to the list of Standing Committees designated under Sec. 1, Chap. 10 of the By-Laws.

I move the adoption of this resolution.

Motion seconded.

Dr. Rooney moved that the matter be tabled. Motion seconded, and carried. (For action, see Section 90.)

## 88. COMMITTEE ON SCIENTIFIC WORK

The Speaker: Are there any other reports of committees?

Dr. Schnell, of Niagara:

Your Reference Committee on the report of the Committee on Scientific Work and on the report of the Committee on Arrangements commends the thorough and painstaking manner in which these committees have performed their duties.

We note with satisfaction the excellent type of scientific program provided both from the standpoint of subject

matter and of distinguished essayists. We consider it a signal achievement that the committee has been able to prevail upon the President of the American Medical Association, Dr. Malcolm L. Harris, to honor this meeting of the Medical Society of the State of New York with his presence.

We endorse the plan of having two general sessions as part of the program of the scientific meetings, where all may have an opportunity of hearing that which is of general interest to the entire profession. As a suitable subject for at least one of these general sessions at future meetings, we suggest a review of medical and surgical ad-

vances during the year.

We approve the innovation of advancing the hour of the first scientific session to Tuesday as worthy of trial. If experience proves this change practical and popular, we recommend its continuance.

We approve the reduction of the price of the annual banquet to four dollars. We disapprove the suggestion that the State Society furnish a free banquet to all registrants attending the annual meetings.

We approve the innovation of the public dinner meeting with the public as scheduled on this year's program for Wednesday evening.

We congratulate the Committee on Scientific Work that it has been able to provide a clinic day at Rochester Hospitals for those wishing to avail themselves of clinics following the closing sessions of the scientific program,

#### 89. Committee on Arrangements

We cite the following paragraph from the report of the Committee on Arrangements and approve the sug-

gestion:

"We have been impressed with the multitude of trivial details which must be carried out by the Committee on Arrangements. While it is easy to segregate various parts of the arrangements and delegate individuals or small groups to care for them, still a clearing house must be maintained for careful checkup. We believe that these detail functions of arrangement should be under the Executive Officer in Albany where supplies and equipment could be stored and handled. With such a centralization of meeting arrangements, some individual or group could take the entire responsibility for the necessary period of time preceding the meeting. Such a group would prob-ably be a business organization, whose function was the carrying on of such arrangements."

We also recommend the following action:

Whereas, permission granted essayists to over-run their time severely curtails the time allotted to the following essayists, therefore, we recommend that Chapter XV, Section 1, of the By-Laws allowing twenty minutes only to the reader of a paper be inflexible; and that chairmen of sections be instructed to rigidly enforce this

I move that this report be adopted. Motion seconded and carried.

# 90. Publications and Medical Publicity

Dr. Rooney: I did not intend that the report of the Reference Committee on the President's Address, in its entirety, be tabled (Section 87); I did not intend that the committee should be prevented from completing the report, and in view of the fact that I have voted to table, I move that we take from the table the report of the committee beyond the first and second paragraphs, and hear their report.

Motion seconded and carried.

Dr. Goodrich: Mr. Speaker, it is a question in your committee's mind just now, as to just what is intended at this moment, for it seems to the committee that the House could not table anything that it never had before it, and I would like to ask what is now before us.

The Speaker: My ruling is that the whole report beyond the first and second paragraph is before us for

consideration.

Dr. Goodrich: In view of Dr. Rooney's remarks con-

cerning the very frank tenor of the preamble, the committee has voluntarily deleted that from the report; I will, therefore, begin with the third paragraph.

Third: That this committee establish a Bureau of

Publicity, as recommended by the President

Fourth: That the committee supervise and control the editing and publishing of the Journal of this Society in conjunction with the editor of the Journal, who shall always be a member of the committee.

Fifth: We favor the adoption of the President's recommendation that this committee establish a liaison with newspapers, magazines and other publications, and furnish them with edited articles, daily or weekly, of what our State Medical Society, or its component parts, are doing in advancing the interests of medicine and public health.

Sixth: We recommend the adoption of the following recast recommendation that this Committee aid and assist the distribution, through the columns open to them of the news concerning activities of organized medicine, and see that it is offered to the lay press.

Seventh: We recommend the adoption of the suggestion that this Committee shall advertise more heavily in general, and where given locally, such post-graduate courses as are offered by the Society to its members, or, where proper, any post-graduate courses of other groups, that the public may acquaint themselves the more, concerning the activities of organized medicine.

Eighth: To issue information when deemed advisable, in pamphlets, by letters, or by other legitimate means, to physicians, lay people, or lay organizations covering important, pertinent, medical topics.

Ninth To undertake the foundation and conduction

of a press bureau as for the syndicating of medical articles such as are appearing at present in newspapers through the country for commercial gain, and to be prepared to answer such letters and inquiries on medical questions as may be directed to the newspapers, or to medical societies so as to forward proper medical advice and induce such questioners to "consult your own doctor, nearest clinic, or your own County Medical Society.

Tenth. To establish a bureau of lay and medical speakers, who, gratuitously or for small honorarium will be prepared to furnish such persons with literature and data on general, and if feasible, special medical topics. This portion of their work shall be subservient to the call of the various committees, Public Relations, Public Health and Medical Education, Periodic Health

Examinations, etc.

Eleventh: We recommend the omission of the consideration of the President's recommendation No. 9.

In his last paragraph the President expresses his appreciation of the honor bestowed upon him by our Society. After the protracted consideration of this important and forward-looking report, and after recalling his long and efficient service in the interests of our Society; and after recalling again that this year of immensely progressive work has been accomplished in the face of serious physical handicaps, we recommend that the House of Delegates here now assembled vote that Dr. James N. Vander Veer has honored our Society in his presidency, and that we appreciate the mag-nificient spirit with which he has worked for us."

The Speaker: Now, gentlemen, what will you do with

this report?

The Secretary: I move that the last paragraph referring to our President, be adopted.

Motion seconded and unanimously carried.

Dr. Rooney of Albany: I move that in accordance with the constitution and By-Laws, that portion of the Committee's report which will necessitate an appropriation, he referred to the Council.

The Secretary: I would call your attention and the attention of the House, to the fact that this whole matter was before us at our last session. It was referred to the Council. The Council appointed a Committee consisting of Drs. Card, Ross and Trick, to investigate the matter and report, and their report was unaumously against the adoption of this matter of a Publicity Bureau, Publication Committee, and for a great many reasons, especially the fact that the cost would be enormous.

I would like to hear from the Committee that recommended that these recommendations be not adopted.

The Speaker: Dr. Ross, as Chairman of that com-

mittee, will you please take the floor?

Dr. Ross: I wish that we had here, the exact wording of the study which we made of this whole matter. There are many features in this report that present a great many difficulties, and involve a considerable cost. To adopt all of them now, would be to not give consideration to any single feature. It is a thesis in industry, not to add new equipment until the old equipment is used to capacity, or until there are new things to be done.

It is a very difficult and uncertain matter, and it is a question of whether it is an advisable thing to create machinery to undertake pieces of work before we know just what work is to be done, and the committee last year in studying this whole matter, believed that it was very much better to continue the present system, until features appeared that had to be taken care of, and after that had occurred, and we were sure that there was something to do, to then create machinery to take care of these features, and for that reason the committee unanimously decided not to endorse the propositions, and the Executive Committee received that report, and there the matter stands.

The Speaker: Has Dr. Goodrich anything further to report on the President's Address?

Dr. Goodrich: Could we hear from Dr. Trick on this

matter, or from yourself?

The Speaker: Occupying the chair, it is not proper for me to say anything. Dr. Trick is in the House. Dr.

Trick, will you please come forward

Dr. Trick: Dr. Ross has covered the ground very thoroughly. It seemed to us that the development of an organization is by evolution. We are not yet making full use of all the different parts of our organization, and the various types of work that have been suggested should not be attempted until we do and our present machinery proves inefficient. I have no further comments to make except that this carries with it a sum of money, and we do not know yet what it means, and there is no justification for doing anything that will add to our financial burdens.

On motion duly seconded and carried the report was

tabled.

#### 91. RELATION OF PHYSICIANS TO DENTISTS

Dr. E. E. Smith of Queens: WHEREAS, Recent years have witnessed an increased appreciation of the dependence of certain systemic diseases on oral conditions and in turn of certain oral conditions upon general nutrition, and

WHEREAS, emphasis has thus been given to the inter-

dependence of the two professions, of medicine and dentistry, Therefore, Bz Ir Resouven, that the Medical Society of the State of New York favors the promotion of closer relations between the professions of medicine and dentistry, and to this end favors the holding of joint medical and dental meetings of the component County Societies with the District Dental Societies throughout the State.

I move the adoption of these resolutions.

Motion seconded. After some discussion the resolutions were referred to Reference Committee on New Business B. (See Sec-

tion 93.)

The Speaker: Is there anything further to come before the House?

# 92. RETIRED MEMBERSHIPS

The Secretary: Yes, sir. I move that the following gentlemen, having reached the age of seventy, and being recommended by the County Societies, be placed on the retired list:

Herman Bendell, Albany; Albert C. Benedict, Yonkers; J. Bion Bogart, Brooklyn; Lewis A. Coffin, New York City; John P. DeLaney, Geneva; Paolo DeVecchi, New York City; Marcus A. Dumond, Ithaca; Grosvenor S. Farmer, Watertown; Paul T. Ferrer, Cameron; John Crocker Fisher, Ithaca; Allen Fitch, New York City: Word B. Hogg New York City. New York City; Ward B. Hoag, New York City; John A. Knapp, Mount Vernon; Henry C. Lyman, Norwich; Edward F. Marsh, Brooklyn; William P. Mason, Troy; Gennaro Merolla, Brooklyn; William P. Northrup, New York City; Lewis S. Pilcher, Brooklyn; Henry F. Risch, Brooklyn; DeWit C. Rodenhurst, Philadelphia; Alexander O. Snowden, Peekskill; Willis A. Tenney, Granville; Edgar C. Wilkinson, New York City; Mark H. Williams, New York City.

Motion seconded and consider Motion seconded and carried.

# 93. RELATIONS OF PHYSICIANS TO DENTISTS

The Speaker: Dr. Kosmak, have you anything to re-

port?

Kosmak: The resolutions which you have just heard introduced by Dr. E. E. Smith, of Queens (Section 91), are approved by the Reference Committee, and I move their adoption.

Motion seconded and carried.

The Speaker: Are there any other committees to report?

#### 94. LEGAL COUNSEL

Dr. Deyo, of Dutchess-Putnam: The Reference Committee on the report of the Legal Counsel (Journal, May 1, page 509) beg to submit the following:

1. The work of the year has been carried along on the lines of previous years, viz. the editorial, case reports, Counsel work with committees, societies and individuals, which have carried out the aims of our Counsel to bring about a better understanding by the public of the physicians' professional, economic and personal prob-

Under the head of Litigation, the committee notes with much satisfaction the reduction of the so-called "Meritorious" suits to twenty-eight and two cases of judgment for

the plaintiff.

These twenty-eight cases settled, involving some real liability on the part of the physician, constitute a real and cogent reason for universal insurance coverage by

the members of the Society.

The Group Plan has shown a steady increase in growth, but there are two recommendations in the report that should be stressed; first, lapse of policy; second, lapse of membership in the Society with consequent loss of insurance.

There has been a yearly increase of 508 members in the Society of whom 406 have availed themselves of insurance, which again demonstrates the success of the

Group Plan.

The retirement of Mr. Stryker as General Counsel of

the State Society is regretted by all the members.

The action of the Executive Committee in requesting Mr. Stryker to accept the position of Consulting Counsel is strongly commended. Because the profession cannot afford to lose contact with a man who has taken such a personal interest in the physician himself.

By virtue of his association with Mr. Stryker in carrying on the legal work of our Society, Mr. Brosman is in every way equipped to fulfill the demands of this po-

sition.

I move the adoption of the Report.

Motion seconded and carried.

The Speaker: Now, if there is nothing further before the House, and before I hear a motion to adjourn, I want.

to announce that the Special Order of Business tomorrow morning is the election of officers, which takes precedence over any other business that comes before the House, and that we will adjourn tonight. The motion must be that we adjourn to a definite hour on Tuesday, June 3rd, 1930.

A motion was thereupon made to adjourn to 9 A. M. on Tuesday, June 3rd, 1930, which motion was seconded

and carried

Adjourned Session of the House of Delegates Tuesday, June 3, 1930

The meeting was called to order by the Speaker at 9 A. M.

95. ROLL CALL

The Speaker: The Secretary will please call the roll. The Secretary called the roll and the following delegates responded:

Frederic C. Conway, William P. Howard, Brayton E. Kinne, Lyman C. Lewis, J. Lewis Amster, Moses H. Krakow, Edward R. Cunniffe, Cornelius J. Egan, Louis A. Friedman, Vincent S. Hayward, Samuel Rosenzweig, Hubert B. Marvin, Perry H. Shaw, Louis F. O'Neill, George W. Cottis, Reeve B. Howland, Anton S. Schneider, Charles D. Ver Nooy, Robert Brittain, C. Knight Deyo, William A. Krieger, Aaron Sobel, John D. Bonnar, Francis J. Butlak, Mary J. Kazmierczak, Charles Leone, Francis J. Butlak, Mary G. Batter, Charles Leone, Charles C. Batter, Charles C. Transp. Edward J. Lyons, Milton G. Potter, Charles C. Trembley, Sylvester C. Clemans, Milton P. Messinger, Frederick W. Goodrich, Norman L. Hawkins, E. Jefferson Browder, Charles T. Graham-Rogers, John L. Bauer, Siegfried Block, J. Earl Miles, Alec. N. Thomson, Peter Dulligan, Harold R. Merwarth, Frederic E. Elliott, J. Richard Kevin, Charles H. Goodrich, Edwin A. Griffin, J. Richard Revin, Charles H. Goodrich, Edwin A. Grinni, Eugene R. Marzullo, Nunzio A. Rini, John E. Jennings, Alexander L. Louria, Walter D. Ludlum, Joseph W. Malone, Joseph Raphael, Simon Frucht, John A. Shields, Luther F. Warren, Fred R. Driesbach, Samuel H. Raymond, Charles R. Barber, Clarence V. Costello Joseph P. Henry, Willard H. Vecder, Floyd S. Winslow, Horace M. Hicks, Everett C. Jessup, Louis A. Van Kleeck, Adelbert B. Allen, Emily D. Barringer, Howard Fox, Ed-M. Hicks, Everett C. Jessup, Louis A. Van Kleeck, Adelbert B. Allen, Emily D. Barringer, Howard Fox, Edward M. Colie, Jr., C. Ward Crampton, Walter T. Dannreuther, Julius Ferber, B. Wallace Hamilton, Albert S. Hyman, David J. Kaliski, Samuel M. Kaufman, Samuel J. Kopetzky, George W. Kosmak, Arnold Messing, William M. Patterson, Wendell C. Phillips, Nathan Ratnoff, Orrin S. Wightman, James W. Smith, DeWitt Stetten, Joseph Subkis, Henry K. Taylor, Terry M. Townsend, Frederick J. Schnell, Richard H. Sherwood, George M. Fisher, Joseph L. Golly, Andrew Sloan, Thomas P. Farmer, Frederick H. Flaherty, Albert G. Swift, Claude C. Lytle, Walter W. Davis, Joseph B. Hulett, Charles Padelford, S. S. Ingalls, Floyd J. Atwell, Thomas C. Chalmers, James M. Dobbins, Edward A. Flemming, William J. Lavelle, L. Howard Moss, Ernest E. Smith, William B. D. VanAuken, Oscar M. Race, Eugene D. Scala, George A. Leitner, W. Grant Cooper, Stanley W. Sayer, George S. Towne, Dudley R. Kathan, William C. Treder, John-J. Beard, Allen W. Holmes, Frederick W. Lester, Leon M. Kysor, Herbert B. Smith, Albert E. Payne, William J. Tiffany, Luther C. Payne, George M. Cady, Luzerne Coville, Mary Gage-Day, Thomas H. Cunningham, Walter S. Bennett, Lucius H. Smith, Harrison Betts, John F. Black Merwin F. Day, Thomas H. Cunningham, Walter S. Bennett, Lucius H. Smith, Harrison Betts, John F. Black, Merwin E. Marsland, Romeo Roberto, William R. Thomson.

The following Officers, Trustees and Chairmen of Standing Committees were present:

James N. Vander Veer, William H. Ross, Floyd S. Winslow, Daniel S. Dougherty, Peter Irving, Charles Gordon Heyd, James Pedersen, John A. Card, George W. Cottis, Arthur J. Bedell, Thomas P. Farmer, Walter A. Calihan, Benjamin J. Slater. James E. Sadlier, Frederic E. Sondern, Grant C. Madill, James F. Rooney, Arthur W. Booth. Harry R. Trick, George B. Stanwix, Charles

·H. Goodrich, Edgar A. Vander Veer, Paige E. Thorn-hill, La Rue Colegrove, Austin G. Morris, Thomas J. Walsh.

Waish.
The following Ex-Presidents were present:
Charles Stover, Wendell C. Phillips, Martin B. Tinker,
Grant C. Madill, J. Richard Kevin, James F. Rooney,
Arthur W. Booth, Orrin S. Wightman, George M. Fisher,
James E. Sadlier, Harry R. Trick.
The Speaker announced that the meeting would proceed

The Speaker announced that the meeting would proceed to the election of officers and the following tellers were announced by the Secretary: Walter T. Dannreuther, New York; Reeve B. Howland, Chemung; Andrew Sloan, Oneida; Aaron Sobel, Dutchess-Putnam; Walter D. Ludlum, Kings; William P. Howard, Albany; Ernest E. Smith, Queens; Luzerne Coville, Tompkins and Edward M. Colie, Jr., New York.

## 96. Election of Officers

The following officers were nominated and elected: The following officers were nominated and elected: President-Elect, Dr. William D. Johnson; First Vice-President, Dr. Henry L. K. Shaw; Second Vice-President, Dr. Joseph B. Hulett; Secretary, Dr. Daniel S. Dougherty; Assistant Secretary, Dr. Peter Irving; Treasurer, Dr. Charles Gordon Heyd; Assistant Treasurer, Dr. James Pedersen; Speaker, Dr. John A. Card; Vice-Speaker, Dr. George W. Cottis; Trustee, Dr. Grant C. Madill; Chairman of the Committee on Scientific Work, Dr. Arthur J. Bedell; Chairman of the Committee on Public Health and Medical Education, Dr. Thomas P. Farmer; Chairman of the Committee on Medical Economics, Dr. George F. Chandler, Chairman of the Committee on Medical Economics, Dr. George F. Chandler, Chairman of the Committee on Medical Economics of the Committee on Medical Residents. Sadlier: Chairman of the Committee on Medical Research, Dr. Joshua E. Sweet.

The following were elected Delegates to the Amer-

ican Medical Association for 1931-1932: Grant C. Madill, John A. Card, Arthur W. Booth, Harry R. Trick, John E. Jennings, James E. Sadlier, Frederick H. Flaherty, Arthur J. Bedell.

The following were elected alternates to the American Medical Association for 1931-1932: Charles H Goodrich, Edward R. Cunniffe, Thomas C. Chalmers, Terry M. Townsend, George W. Cottis, Edward M. Colle, Jr., Andrew Sloan and George R. Stanwix.

#### 97. SURVEY OF MORBIDITY FROM HEART DISEASE

The Secretary then presented the following resolutions:

WHEREAS, the Division of Vital Statistics of the New York State Department of Health plans to initiate a continuous survey of morbidity from heart disease in the State, outside of New York City, and

WHEREAS, they desire the cooperation of the physicians in the State in collecting this information, there-

fore, be it

RESOLVED, that the House of Delegates approve the plan and urge the physicians to cooperate so far as possible in the collection of this data.

The Secretary: I move that the resolution be indorsed. Motion seconded and carried.

#### 98. Invitation to Hold Annual Meeting in KINGS COUNTY

Dr. Ludlum, Kings, invited the Society to hold the next annual meeting in Kings County.

The Speaker: That will be referred to the Council. On motion duly seconded the House adjourned sine

> JOHN A. CARD, Steaker. DANIEL S. DOUGHERTY, Secretary.

# **NEWS NOTES**

# TRI-STATE CONFERENCE

The fifteenth regular session of the Tristate Medical Conference was held at the Penn Athletic Club, May 24, 1930, with Dr. William T. Sharpless, President of the Medical Society of Pennsylvania, presiding. Those in attendance were:

New York: William H. Ross, Brentwood, L. I.; Joseph S. Lawrence, Albany; John J. Jennings, Brooklyn; Harold Rypins, Albany. Pennsylvania: William T. Sharpless, West

Pennsylvania: William T. Sharpless, West Chester; Ross Patterson, Philadelphia; Frank C. Hammond, Philadelphia; Harry W. Albertson, Scranton; Arthur C. Morgan, Philadelphia; William Pepper, Philadelphia; Edgar S. Buyers, Norristown; H. W. Mitchell, Warren; William Pearson, Dean of the Hahneman Medical School, Philadelphia; Paul Raymond Correll, Easton.

New Jersey: Andrew F. McBride, Paterson; George N. J. Sommer, Trenton; J. N. Morrison, Newark; Charles B. Kelley, Jersey City; E. C. Taneyhill, Philadelphia, Pa.; Henry O. Reik, Atlantic City.

The subject of the Conference was "Medical Practice Acts, State Boards, and Licensure in the Healing Arts," and was introduced by Dr. Ross V. Patterson, Dean of Jefferson Medical College, and President-elect of the Medical Society of the State of Pennsylvania.

The following abstracts will indicate the scope of Dr. Patterson's remarks:

"It has been said, and I think truthfully, that medical education is usually 25 years ahead of medical practice; and that medical practice is 25 years ahead of medical licensure. The educational problems of 25 years ago are almost completely solved. Whatever remains unsolved can best be left to the medical schools and to their organizations—the Association of American Medical Colleges, and the Association of American Universities.

"The Federation of State Medical Boards, aware of changed conditions, revised its Constitution and By-Laws, February, 1930, so that they now contain the following provisions:

"In all matters of premedical education, courses of study, and education requirements for the degree of doctor of medicine, or its equivalent, the federation recognizes the Association of American Medical Colleges as the standardizing agency for this purpose. The federation regards as its proper function (a) the determining of fitness for the practice of

medicine, and (b) the enforcement of regula-

tory measures.'

"The best law is one of simple construction conferring upon the body responsible for its administration, the broadest possible powers containing the fewest possible number of specifications and restrictions. The present medical practice act in Pennsylvania has become very complex by reason of numerous additions, amendments and modifications, in the various attempts which have been made to incorporate in the act itself changes and advances in medical thought. This has lead to difficulties in understanding its provisions, and consequent difficulties with regard to its enforcement.

"Almost since the organization of medical boards, their chief activity has been that of granting licenses to medical graduates by examination, reciprocity, or endorsement of credentials. Comparatively little attention has been given to the regulation of medical practice.

"State boards need no longer burden themselves with the laborious and tedious examinations of the recent graduates. Written tests have a very limited value as a test of qualifications for admission to medical practice. To my mind, the abandonment of them except in the case of limited groups would be a great step forward.

"So-called basic science laws of various forms have been enacted into law by six states and the District of Columbia during the past four years. There is no agreement as to what sciences shall be considered basic, nor is there uniformity as to the administration of the law. It has been effective in excluding from licensure the most ignorant of the cultists, although renegade medical students have found in this law an opportunity to enter upon the the practice of medicine in a round-about way. under conditions less exacting than would have confronted them in the usual and ordinary course of procedure. Basic science laws raise the standards for cultists and lower them for medical men. Obviously the qualifications of several hundred medical men admitted to practice each year are of more importance than the qualifications of cultists who, even if licensed, assume only a small part of the responsibility for medical care. So far as the recent medical graduate is concerned, he may be licensed by endorsement of his

diploma without detriment to the public in-

terest.

"Prosecution of violators of the law should be a responsibility of the department of jus-

"A deputy attorney-general should be specially assigned to this duty, and should make a special study of medical law enforcement. County district attorneys are often indifferent or inefficient and object to local influences which make them disinclined to prosecute offenders morally supported by influential persons in their home communities.

"Essential to the enforcement of any medical practice act is a corps of full-time specially trained investigators directly under the direction of the administrative board and responsible to it for the performance of their duties. They would have to do with illegal practice of all kinds on the part of both licensed and

unlicensed practitioners.

"There should be compiled, published and distributed periodically a directory of all those licensed to practice any form of the healing art. The information contained in such notice to those interested is of inestimable help to law enforcement. The omission of a name from such a list at once calls attention to an illegal practitioner. It makes a potential investigator of every licentiate who may supply valuable information to those directly responsible for law enforcement. In time the public would come to know of such a list, and would consult it to determine the status of those about whom there was doubt. Such a directory should be in the waiting room of many physicians.

"The pecuniary contribution to law enforcement is an additional advantage. I am aware of the objections to imposing upon those licensed any considerable part of the burden of law enforcement. Whatever theoretic objections there may be, they are far outweighed by practical considerations. Annual registration is now required by twenty-one states while several others require an occupational tax, which in the state of North Carolina amounts to \$25 per year. My personal view is that the registration fee should be about sufficient to cover the expenses of conducting the registration itself, publishing, printing and distributing a directory.

"It is obvious that no medical practice act, no matter how well conceived and constructed, and no administrative board, no matter how carefully selected and talented it may be, will be effective in licensure, regulation and law enforcement unless funds adequate to the financial needs of such an undertaking are budgeted, appropriated and placed at the disposal of such a board."

Dr. John E. Jennings of Brooklyn, in discussing Dr. Patterson's paper said:

"Pennsylvania has been somewhat backward in accepting what we in New York have come to call "Flexnerism," and I use the word without hesitation. In other words, we have come to witness confusion in New York State between education and training. I think Philadelphia has clung to the old Greek idea. I think this has a very close relationship to what Dr. Patterson has proposed and is attempting to do.

"Why is it that specialization has increased? One of the reasons is because of the smaller schools which have found it harder to exist. Many of them were unworthy of existence, but in Massachusetts they have recently been attempting to rehabilitate some of the smaller schools. The country boy who used to go to the small town school does not go into medicine any more; and medicine in New York State is very largely recruited from the urban population, with lower ethical standards and ideals. Perhaps, after all, medicine is best learned at the bedside. Perhaps the basic sciences are not so important as actual contact with the preceptor. Is it not possible to go too fast and too far in this matter?

"I think that an attempt to protect the public from cultists by a board of education is impossible. An investigator, a little bureaucracy, attempting to cull out the licensed practitioners and to prevent the illegal practitioners from practicing seems to forget that the citizen believes he has a right to consult any one he likes and that he will simply put the chiropractor, the more this law is enforced, into the unhappy position of a bootlegger. It will simply cost him a little more to fix your in-

vestigator, that is all."

Dr. Andrew F. McBride of Paterson, President of the Medical Society of New Jersey, said:

"Referring to the inclusion of osteopaths on such a board brings to mind the New Jersey board. We have an osteopath, a chiropractor and an eclectic member on our board. They deal with subjects peculiar to their cults. We have no 'dual board.' The chiropractors previously had a separate board.

"Annual registration is a moot question. Personally, I have no objection to it, but many others have and for what they believe good

and sufficient reasons."

Dr. Harold Rypins, Secretary of the New York State Board of Medical Examiners, said:

"The trouble with most medical practice acts is that they have been written without a clear idea of what the act is to accomplish. They attempt to protect the public health by giving the right kind of physicians to the state.

There are three things you must do to get the right kind of physicians; first, to train and license the right men; second, to take out those who have not behaved properly; and third, to keep from practicing those who do not meet the qualifications. Every medical practice act must have these three assets and each of them must work successfully; these three things must be integrated. I know of no way in which that can be done unless the whole thing is embodied in one act and that act is administered by one board or body.

"Because of the large amount of work involved, in New York we have split up and now have a board of medical examiners which does nothing but examine applicants for licensure. and we have a Grievance Committee which does nothing but handle case of discipline. That is made up of ten of the leading physicians of the state who serve without compensation, for the good of the profession. It holds legal hearings and recommends the proper discipline to the Board of Regents of the state education department. Only once have the Regents disagreed with the Grievance Committee. The moral effect of this committee has been very great. It has been operating since September, 1928, and has considered 119 cases of charges against licensed physicians.

"Where, ordinarily, people would employ a shyster lawyer and have a law suit, they have now found that without hiring a lawyer they can come before this committee and air their grievances. It has been very valuable to the profession and is a by-product which we did not anticipate. All of the cases listed as malpractice, practically all listed as miscellaneous, and all listed as unethical conduct, have been complaints of people who would ordinarily bring a law suit against physicians, and instead of that they have come before this committee, had the situation explained, and gone away satisfied."

Dr. Charles B. Kelley of Jersey City, speaking for the Medical Examining Board of the State of New Jersey, discussed some of the difficulties which New Jersey had with the State of Pennsylvania over the licensing of candidates, and said:

"Because of various classifications conflicts between the state boards have arisen, and Pennsylvania has been the storm center. New Jersey is not the only state that has this difficulty for Pennsylvania has had quarrels with half a dozen different states regarding this subject. The Pennsylvania Board has never seen fit to accept any classification except its own; saying the board cannot, according to the law, accept the classification of any body such as the A.M.A. or the American College of Sur-

geons. Consequently when we broke off relations with Pennsylvania, in 1925, it was over nothing but the intern year. We still accepted Pennsylvania graduates if their intern year had been served in a hospital which we could accept. That went on until within the last year we felt that we had settled it. The Pennsylvania Board still holds to the position that it cannot accept any internship except in a hospital inspected and approved by its own inspection. We have adopted as our classification for the graduate in medicine the fifth year training for the graduate, and the A.M.A. classifications. We will accept an internship in any hospital in the United States approved by the A.M.A. for intern training. That includes Pennsylvania also. And we hope that Pennsylvania will some day or other extend us the same courtesy."

Dr. Harry W. Albertson of Scranton, past-President of the Medical Society of the State of Pennsylvania, said:

"The fact that two states have repealed their basic science laws recently leads me to believe that these laws are not what we would first have believed them to be. I do not think that they work out well. I have tried to keep in touch with the secretaries of the boards of the states that have had basic science laws and I am led to believe that they are not the best means of keeping out those who would come into the medical profession by the back door.

"In the matter of reciprocity, that seems to have been a very good subject for this morning's discussion. I do not see how you are going to have reciprocity with other states where there is a difference in laws, not a difference in the matter of interpretation of laws, but a difference in the reading of the laws. If a board of medical education and licensure is going to be of any service to the people and to the medical profession, that medical profession must have had something to do with the drafting of the law under which they wanted it to work."

Dr. J. B. Morrison, Secretary of the Medical Society of New Jersey, said:

"With regard to the financial application of this law, we have never been able to convince the department of justice that it should appropriate money for the prosecution of illegal practitioners. We have been, perhaps, looked upon as a 'medical trust' attempting to protect our own pockets. Four years ago we tried to pass an annual registration act in New Jersey and it would have gone over had it not been that the state board of medical examiners the year before had attempted to pass a similar act containing the statement that if a man failed to register they could revoke his license. That killed annual registration in New Jersey. It has been adopted now in twenty-one states and I believe after a few years more we may be

able to put it through in New Jersey.

"I believe also that the New York bill has another excellent feature for medical men. We tried to pass that act also in New Jersey but could not do so because we had already recognized for chiropodists the title of doctor-surgeon-chiropodist. That was done because the only decent school of chiropody in America was in Philadelphia and we accepted its graduates with that title, so could not take it away from them."

Dr. William Pepper, Dean of the University of Pennsylvania Medical School, said:

"The question of money for the carrying out of one of the duties of state boards, that is the prevention of illegal practitioners and the prosecution of them, etc., I agree heartily with those who feel that this money should come from the state. I do not see why the doctors in the state should be assessed to carry out that work. I approve of annual registration."

Dr. William Pearson of Philadelphia, said: "Obviously, I represent a minority in medical education, representing the homeopathic branch of the school of medicine. The chief criticism I would have of Dr. Patterson's proposal is that absolutely no recognition whatever is suggested for the homeopathic school. We in Pennsylvania represent approximately 10% of the physicians. We have our own state society which is very flourishing and a fine organization. There is no question in my mind that my colleagues would criticize me were I not to mention this apparent oversight."

Dr. Paul Correll, Easton, Pa., said:

"We could clean up Pennsylvania in six months if we had the funds with which to prosecute irregular practitioners; and we must clean our own house, get rid of the regulars who are guilty of misconduct, as well as attack the cults. I am sure the Pennsylvania Medical Society would welcome a Grievance Committee. We need, too, to have our law amended and made so definite that there will be no bickering over the crossing of a 't,' or the dotting of an 'i,' for we not only have had difference with the New Jersey board, but have had differences of opinion among ourselves."

Dr. J. B. Morrison read a letter from Dr. Olin West, General Manager of the American Medical Association, whose opening para-

graph was:

"At the Portland Session Dr. William Allen Pusey introduced a resolution that was adopted by the House of Delegates providing for the compilation of a comprehensive statement for the guidance of the American Medical Association concerning the practice of medicine by corporations, by clinics, by philanthropic organizations, by industrial organizations, and concerning the relationship of physicians thereto."

It was voted that this matter be referred to a special sub-committee.

The meeting was in session from 10.30 A.M. until 2.45 P.M. with a brief intermission for luncheon. Those in attendance were guests of the Medical Society of the State of Pennsylvania.

# TIOGA COUNTY

The regular dinner meeting of the Medical Society of Tioga was held at the Jenkins Inn, Waverly, Tuesday evening at 6:30. The following members and guests were present: Dr. Frederick Terwilliger, President, Spencer; Dr. W. A. Moulton, Secretary, Candor; Drs. A. J. Capron, G. M. Cady, E. E. Bauer, L. D. Hyde, of Oswego; Drs. Guy Carpenter, F. A. Carpenter, L. S. Betowski, P. D. Bailey, F. H. Spenser, M. D. Baxter, of Waverly; Drs. C. H. DeWann, J. W. Higgins, S. D. Conklin, of Sayre; Dr. Amos Canfield, of Candor; Dr. E. M. Cowell, of Athens; Dr. James Cargill, of Van Etten: M Delos Goodrich, Superintendent of Schools in the Second Supervisory District; Fred G. Frost, Newark Valley, Chairman of the County Fair Commtitee; Miss Margaret Dake, School Nurse, Waverly; and Miss Elizabeth Pinney, County Public Health Nurse.

The President introduced Mr. Goodrich, who spoke of the great necessity of school nurses for the rural schools. He gave a summary of the defects found by the examining physicians in his District for the last year,—776 pupils examined; 684 defects found; of these only 123 had treatment. He felt that a full time nurse for the schools would do a great deal toward correcting this condition. The Medical Society voted as being in favor of school nurses.

Then followed a discussion of a preventative health program to be arranged for the County

Fair, which will be held in Oswego during the week of August 18th. Mr. Frost, Chairman of the Fair Committee, offered to donate space and to cooperate in any way to make the plan a success. It was voted that the Public Health Committee of the Medical Society work out a plan and make arrangements for the project.

Dr. Frederick Carpenter then introduced the speaker of the evening, Dr. Hilton J. Shelley, full time Health Officer of Middletown, N. Y. Dr. Shelley's topic was "Undulant Fever," which, he said, according to history was nothing new. In 1567, England had the disease, but it was not recognized as such. The Board of Health in Middletown publishes a monthly bulletin which is very instructive and much in demand. Every month twenty-five copies are sent to foreign counties.

Dr. Shelley gave a report of several cases which he had seen and showed the importance of pasteurizing milk, it being the only means of prevention. The economic benefit to the farmer is large, and he is starting a campaign to help the farmer.

Then followed a general discussion in which several physicians took part.

The Society voted to invite the Sixth District Branch of the State Medical Society to hold its Fall meeting in Tioga County.

The meeting was then adjourned until September.

W. A. Moulton, Secretary

# BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on May 21, 1930, was called to order at 9 P.M., the President, Dr. Aranow, in the Chair.

The following candidates were elected to membership: Drs. Maxwell C. Ballen, Alfred B. Clements, Thomas L. Crescenzi, Anthony J. Giordano, Nicholas A. Gnazzo, Alexis Gottlieb, Salvator G. Maraventano, Morris Sonberg, Louis F. Soscia, Morris Tannenbaum and Philip Weisberg.

The following proposed Amendments to the By-Laws were submitted: Add to Section 4, beginning at nineteenth line:

"Internes serving in Bronx Hospitals are

also eligible for Associate Membership in this Society."

Add Section 26 (a):

"Applications of Internes for Associate Membership shall state college from which graduated, with date and hospital affiliation. An affirmative vote of two-thirds of the votes cast at a regular meeting of the Society shall be necessary to elect."

The Scientific Program then proceeded as follows:

Paper: Psychiatry in Relation to General Medicine—Menas S. Gregory.

I. J. LANDSMAN, M.D., Secretary

#### CLINTON COUNTY

The 'semi-annual meeting of the Clinton County Medical Society took the form of an evening banquet at the Monopole Grill, Plattsburgh, N. Y., on May 20, 1930. Attendance twenty.

The Committee on Public Health and Public Relations gave a report which was a preliminary report on the maternity survey of Clinton County for the year 1929. Of 1,060 questionnaires sent out to all physicians reporting, births in the calendar year, 696 had been received. It was expected that this number would be brought up at least 90% within a short time. Some interesting points were brought out in the discussion of this preliminary report and it was decided that the Committee should continue.

An amendment to the by-laws raising the annual dues to \$5.00 was presented, to be acted upon at the annual meeting to be held in

A discussion on the matter of physicians' fees for County and Town cases resulted in referring this matter to a Committee for thorough consideration and report, as was also the matter of hourly nursing.

The President spoke of the matter of insurance under the State group plan. This was discussed by Dr. L. G. Barton, a Vice-presi-

dent of the State Society.

Following the business meeting entertainment was provided in the form of an address by Mr. Harry P. Kehoe, a local attorney.

LEO F. SCHIFF, Secretary.

#### FRANKLIN COUNTY

The regular semi-annual meeting of the Medical Society of the County of Franklin was held June 11, 1930, in the John Black Memorial Room at Saranac Lake. Luncheon was served in the Hotel Saranac.

At the business session the following officers of the County Society were present:

Dr. Edward S. Welles, President in Chair. Dr. Philip E. Stamatiades, Vice-president. Dr. George F. Zimmerman, Secretary-

Treasurer. Dr. J. Woods Price and Dr. G. C. de Grand-

pre. Censors.

Members present: Drs. Kinghorn, Dalphin, H. B. Brown, Brumfiel, Packard, Eagan, Heise, Emans, Wilding, de Grandpre, Kissane, Leetch, Haskins and White.

Visiting Doctors: Dr. S. W. Sayre, Sanitary Supervisor for Northern New York District, Gouverneur, N. Y.

Dr. Edwin M. Jameson, Saranac Lake. Dr. Robert W. Kropp, Columbus, Ohio.

Dr. Herman J. Wytie, Bloomington, Ind. Dr. James S. Edlin, New York City.

Dr. John Duffy, Dublin, Ireland, Dr. Spencer Schwartz, Trudeau, N. Y.

Dr. John Fabian Busch, Spartanburg, S. C.

Dr. David T. Smith, Ray Brook, N. Y.

Dr. William M. Gay, Saranac Lake, N. Y.

On motion the President named the following committee to nominate officers for the coming year-Drs. Kingborn, Dalphin and White,

The following officers were nominated and elected in open meeting:

President: Dr. Dhilin E Stamatiadae M.D.

Vice-President: H. Beattie Brown, M.D. Secretary-Treasurer: George F. Zimmerman, M.D.

Censor for three years: L. P. Sprague, M.D. Delegate to Annual Meeting: C. C. Tremb-

ley, M.D. Alternate: J. E. White, M.D.

The following new members were elected:

Charles H. Haskins, Saranac Lake.

Joseph T. Eagan, Saranac Lake. C. C. Trembley, County Delegate to the State Meeting held in June, 1930, reported on the discussions on the Workmen's Compensation Act.

The Scientific Session was well attended, and keen interest was manifested in the papers and discussions.

1. "Vitamins in Their Relation to Disease," by David T. Smith, M.D., Ray Brook, N. Y.

Dr. Smith showed by original experiments the effects on animals of withholding certain vitamins from their diet and the spectacular return to normal when these vitamins were restored. The paper was discussed by Drs. White and Kissane.

2. "Some Pitfalls in Diagnosis Encountered by the General Practitioner," by J. W. Kissane,

M.D., Malone, N. Y.

Dr. Kissane in his address gave many helpful suggestions in arriving at a diagnosis in various cases of obscure conditions in infants and young children. Discussion by Dr. Welles,

3. "Case Report, Tuberculous Meningitis," by John E. White, Malone. Discussion by Drs.

Dalphin and Heise.

G. F. ZIMMERMAN, Secretary.

# THE DAILY PRESS

# WORDS AND ACTIONS

J. N. Ding might have had the medical profession in mind when he designed the cartoon for the New York Herald Tribune of May 9, 1930, entitled "What really worries him." Perhaps some physicians will wonder what possible connection that cartoon can have with medicine. When we saw the cartoon our first reaction was that it taught that the average doctor considers pulling dandelions from the lawn to be a highly commendable response to the reformer's call to action; but deeper thought revealed a subtle allusion to the difficulty of practicing preventive medicine.

It seems easy to get rid of dandelions. One can dope the ground with salt, but that kills the grass also; or one can practice surgery on them, but the roots have a mighty hold upon the soil; or one can try to exclude the seeds from the soil. But dandelions and sickness will both flourish long after reformers have given up the idea of their eradication.

There will always be a call for the skilled surgeon who can remove diseased tissues, and the internist who brings comfort and relief with his ministrations. Modern conditions of living bring new forms of sickness; and nervous diseases will increase even though physical changes are prevented. It is certain that the family doctor will continue to be called out of bed by his suffering patients.

# ENLIVENING STATISTICS

Vital statistics may be the basis of public health work, but they are about as interesting as the bricks in the cellar walls of a house. How to endow statistics with vital interest to the average reader is a problem that is wellnigh insoluble. How a City Manager in California tried to solve it is told in the following editorial from the New York *Times* of April twenty-first:

"People have been spoiled for difficult reading by the brief, pithy, breezy style of writing so generally cultivated nowadays. They will not take the time to dig patiently into a long, dull report in order to get at the interesting or essential facts in it. The City Manager of Berkeley was distressed because no one was reading the news of admirable improvements in the bright part of California of which he has charge. All the municipal news was of the

most gratifying kind, yet the citizens paid no attention to his facts and figures.

"In a moment of inspiration he called on a San Francisco newspaper man for help. This writer was experienced in dressing up a mild little story with frills of human interest, and advised a similar method for the city statistics.

"The next municipal reports appeared in the form of a small newspaper with oversize headlines. Mr. Weigle found and played up the most striking features of garbage collection, police activities, health problems and street paving. Trifling but amusing or significant occurrences in all departments were used to introduce the heavier matters in which the taxpayers should have been interested. The result has been that every one in Berkeley wanted a copy of the report. In addition many governmental bureaus all over the country and several abroad have sent for copies."

#### INTELLIGENCE TESTS

The value of intelligence tests has often been disputed and they have been condemned because they are only about seventy-five per cent infallible. We do not agree with the writer with whom the following interview is published in the New York Times of June 22:

"The intelligence test is one of the greatest crimes that was ever foisted on the public in the name of education, according to Joy Elmer Morgan, editor of The National Educational Association Journal, just before he left New York yesterday for Washington, D. C.

"It is not an intelligence test at all.' Mr. Morgan said, 'because it does not measure intelligence. Lincoln and many other great thinkers of the past would have been rated very low by such a test because they were deliberate thinkers.

"'What these tests do measure is a person's ability in a particular, narrow field at a particular time. They do not measure intelligence because they do not make allowances for the constant changes in a person's background, intensity of purpose, thoroughness and rate of thinking. All of these are essential factors in

the make-up of a person's intelligence,' he

pointed out.

"The fallacy of using the Binet-Simon tests in rating the American soldiers during the World War was also scored by him. On the basis of these tests the average soldier was rated as possessing an intelligence of a 12year-old child.

"'This is obviously ridiculous,' Mr. Morgan said. 'Especially does it become foolish when we remember that educators are fairly well agreed on the point that the human mind ma-

tures at the age of twelve.'

"The vicious effect of these tests in the educational program of our schools and colleges today lies in the fact that they have discouraged those who have needed the encouragement most and made 'smart alecks' out of those who most needed to face difficult tasks. The deliberateness, thoroughness and the abilities to analyze and think reflectively do, after all, form the basis of greatness."

Yet intelligence tests will justly continue to be given and the results applied in teaching, in the selection of candidates for positions, and

in numberless other practical ways.

#### THE PHYSICS OF NERVE ACTION

When someone makes a new observation on the action of a part of the body, the public are prone to consider it as an explanation. Nerve action is mysterious, but some phases of it have recently been made visible. The New York Herald Tribune of June 22, commenting on the observation says:

"The experiments on the effects of alcohol, anesthetics and other substances on nerve tissues, reported at the Colloid Symposium at Cornell University by Dr. G. H. Richter, provide a not unexpected confirmation of the suspicion long prevalent among physiologists that the inner substance of a nerve and the colloid materials typified by gelatin and white of egg have many properties in common. Nerve action has been mysterious because it evidently involves two different but associated actions. On one side, the operations of a nerve are indubitably electrical."

"What Dr. Richter now has accomplished is the detection of a change in nerve cells, visible under a special form of microscope, which change occurs when the account of the change commission by an anesthetic like chloroform, by a toxic agent like alcohol or even by severe shaking or other mechanical stress. The change is a coagulation of the colloidal matter of the living nerve cell, apparently much the same thing as the coagulation which makes white of an egg turn hard and white when it is cooked. In the nerve cell, however, the coagulation is not permanent, but disappears slowly when the anesthetic or other agent is removed.

"It is known, too, that such changes, even in non-living colloids like glue or silica jelly, often are accompanied by electrical effects, which provides the link between the new observations of Dr. Richter on nerves and the known electrical actions of these organs. Possibly the chemical factor of nerve action, already known to accompany the electrical one, is merely this coagulation of the nerve cells. In any event, the microscopic method which Dr. Richter has perfected for seeing these things happen promises much for better knowledge of the actions of these master tissues of all animal life."

## OUR NEIGHBORS

#### LEGISLATION IN NEW JERSEY

The June issue of the Journal of the Medical Society of New Jersey describes a meeting of the Welfare Committee held on April 27, at which the following report on legislation was

given:

"The General Assembly of New Jersey has adjourned without having done any harm to the health laws of the state. Of the various bills pending at the time of our last meeting, March 2, those bills to which we had given endorsement have, with one exception, become part of the statutory laws, while those to which we filed objections all failed of passage.

"To be more specific: A1, continuing the work of the Commission on Crippled Children, was passed; A 3, requiring the signing of death certificates by physicians within a time set for burial of the decedent, was passed; A 85, providing higher educational requirements for students of chiropody, and defining the limitations of chiropody practice, was adopted after amendment in accordance with an agreement made with a special subcommittee of this body; S 207, compelling reports to be submitted promptly to local boards of health when persons are bitten by dogs or other animals subject to rabies, was passed; S 117, providing for aliens in favor of hospitals furnishing treatment to patients injured in accidents, was passed. It is to be noted that this last-mentioned bill protects a hospital but makes no reference to physicians or nurses. A corresponding bill intended to cover physicians and nurses as well as institutions—A 284. -was not further considered after it was agreed here to support S 117. A 202, controlling Expert Testimony was passed in the House of Assembly, but defeated in the Senate.

All of the osteopathic, chiropractic and nauturopathic bills were defeated on the floor of the Assembly or were held in committees. A 93, designed to regulate the practice of surgery in its several branches, was killed

in committee."

#### POPULAR MEDICAL EDUCATION IN ILLINOIS

The Illinois Medical Journal of June describes the popular medical education work of the State Society in the following editorial:

"Few state medical societies enjoy and profit from contacts with lay organizations in the degree afforded the Illinois State Medical Society through its educational committee. That intelligent understanding existing between the medical profession of Illinois and these lay groups has been valuable to all concerned.

"The Public Health and Child Welfare Chairman of the Illinois Federation of Women's Clubs and the Illinois Congress of Parents and Teachers, representing about 200,-000 women, confer with representatives of the Educational Committee. Some excellent work is being done by these two splendid groups of women. Particular mention might be made of the "Summer Round-Up" and the correction of remedial defects following physical examinations at that time. Hundreds of physicians have been invited to appear before women's clubs and Parent-Teacher Associations in order that the members may learn what medicine has accomplished and is doing to raise our health standards. The Illinois Federation of Women's Clubs supported the

State Medical Society in opposing the Sheppard-Towner Act and opposing anti-vivisec-

tion legislation.

"The University of Illinois Home Economics Extension Service has sought the advice and assistance of the Educational Committee in its work with the Home Bureaus and 4H clubs. In a number of counties all Home Bureau Units have received some cooperation

from the State Medical Society.

"The Chicago Woman's Club, with its cancer program, the Chicago Section of the National Council of Jewish Women; the Chicago Woman's Aid; the Jewish People Institute, the Juvenile Detention Home sponsoring proper sex education; the American Public Health Association; the Illinois State Dental Society, and the Elks Foundation for Crippled Children should also be mentioned. Evanston Woman's Club, through Mrs. Rufus Dawes, came recently to the Educational Committee for advice and cooperation. There can be no question as to the value of these contacts which have helped so much in promoting an intelligent interest in important health problems of Illinois. (Continued on page 808adv. xvi.)

## Whereas

The physicians of this country evidence an almost unanimous preference for Dextri-Maltose when modifying Protein Milk, as well as cow's milk formulae

The Cardiologist's Choice

Pil. Digitalis

(Davies, Rose)

Physiologically tested leaves made into physiologically tested pills.

Convenient, uniform and more accurate than tincture drops.

Prescribe "original bottle of 35 pills" which protects the contents from exposure from the time of manufacture to the time of administration. This further insures dependability of action.

Each pill contains 0.1 gram, the equivalent of about 1½ grains of the leaf, or 15 minims of the Sample and literature upon request.

DAVIES, ROSE & CO., Ltd. Pharmaceutical Manufacturers, BOSTON, MASS. (Continued from page 806)

"The Illinois State Department of Public Health enjoys friendly relationship with the State Medical Society. Its various divisions have sought and received cooperation from the Educational Committee. The members of the Committee and several obstetricians checked over and revised the prenatal letters now being sent out by the Child Hygiene Division. Numerous appointments have been filled for the Division of Public Health Education and that Division in turn has supplied posters, films, and literature to the Educational Committee. There seems to be much less conflict than in former years between the medical societies and the nurses sent out from the State Department of Health.

The Committee has been represented on the Advisory Council of the Child Hygiene Division of the State Department of Health. This Council has officially approved a plan for work which will require the cooperation of the county medical society, county dental society, and local lay groups. Several counties are considering the establishment of this plan within

the near future.

"The contacts which the medical society has had with grade schools, high schools, colleges, with Y.W.C.A.s, with the men's service clubs and with young mothers' clubs, have given individual members a new understanding of what the Illinois State Medical Society is trying to do. Practically every lay organization of any appreciable size or importance in Illinois has had contact with organized medicine. During Health Promotion Week, 1930. members of the Illinois State Medical Society presented health programs to over two hundred schools, clubs and churches."

#### NEBRASKA STATE SOCIETY MEETING

A description of the Annual meeting of the Nebraska State Medical Association held in Lincoln, May 13-15, is contained in the June issue of the Nebraska State Medical Journal which says:

"The annual meeting at Lincoln, May 13, 14, 15, is history, and history of one of the most profitable meetings ever held. The registered attendance was 389, which owing to heavy rains and flooded streams west, was quite remarkable.

"The House of Delegates performed service of outstanding importance. 'Fraud by Air' was thoroughly ventilated and action taken by the House to make our impress felt before the Federal Radio Commission. A By-Law was passed establishing a Medical Student Loan Fund available to worthy, needy Nebraska

medical students in the junior and senior years, beginning with \$500, and creating a committee to administer the fund.

"Until very recent years an annual meeting of the State Medical Association meant a formal program of several days of the State Medical Association, ending in a banquet. Nowadays an annual meeting is a part of a medical activities week chockfull of clinics, meetings of organizations allied to medicine, and health education of the lay public, to the benefit and convenience of all.

"State Medical Week at Lincoln this year opened Monday, May 12, with a day of clinics celebrating the opening of a new wing to the Bryan Memorial Hospital—which now has 100 beds—with a full program presented by out-of-state medical celebrities.

"The Nebraska Tuberculosis Association had an all-day meeting, May 12, climaxed by a banquet at the University Club. The principal speaker was Dr. J. A. Myers, president of the Minnesota Public Health Association.

"The Nebraska Association of Medical women met on the afternoon and evening of May 13, had a program of three numbers, and a buffet dinner at the residence of Dr. Inez C. Philbrick.

"Health Week was celebrated in Lincoln under the direction of Dr. E. R. Hays, chairman of the public activities committee of the Nebraska State Medical Association, by short talks by visiting physicians on various subjects related to health, before 26 organizations—churches, high schools, luncheon clubs, and business men's clubs and a tremendous amount of good must result from the dissemination of correct information in this way.

"The Nebraska Academy of Ophthalmology and Otolaryngology held its annual meeting and banquet on the evening of May 12.

"The Woman's Auxiliary to the Nebraska State Medical Association had a successful meeting and a number of enjoyable functions."

#### LOANS CORPORATION IN NEW JERSEY

The Welfare Committee of the Medical Society of New Jersey on April 27, made a report on a plan of a corporation to loan money to patients to pay their doctor bills. This report is printed in the June issue of the Journal of the Medical Society of New Jersey which says:

"The subcommittee on the Gilbert Acceptance Corporation had an interview a few weeks ago, with the President and one of the directors.

"The corporation, we find, has two purposes. The one most stressed is a plan to finance the

accounts of physicians and dentists by loaning money on the secured note of the patient, the note to be paid by instalments extending over a period of 10 months. The note must be secured by two responsible endorsers or by good collateral.

"There is no apparent objection to this plan, provided it is conducted by men of ability and integrity with adequate financial backing. However, we doubt that there are many physicians who would not gladly extend credit directly to their patients if given a secured note, without the intervention of a financing corporation.

The second purpose is to sell stock in the corporation. Its capitalization is 25,000 shares. This is offered at \$20 a share. When we asked Mr. Gilbert how much of the stock had been paid for, he admitted that none of the capital had been paid in. When asked for a financial statement of the company, he was unable or unwilling to furnish one. Endorsement of this company by the Welfare Committee would undoubtedly be an aid in selling stock to our members. As an investment the stock must be classed as very speculative.

"The subcommittee feels that it would be unwise for the Welfare Committee to give its endorsement to any venture of this sort."

## ADVERTISING BY COUNTY MEDICAL SOCIETIES IN INDIANA

The May issue of the Journal of the Indiana State Medical Association contains the following comment on Medical Society advertising which doubtless represents the point of view of the physicians of Indiana:

"The Chicago Medical Society is contemplating an advertising campaign, to offset the distorted views concerning the aims and ideals of the medical profession as presented by the average newspaper editor. As a suggested start it is proposed that the oath of Hippocrates be reproduced in a full-page advertisement in the Saturday afternoon and Sunday morning papers of one week. The next week the advertisement will contain a brief history of organized medicine in general.

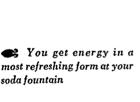

"In another week the Code of Ethics of the American Medical Association will be printed so that the public will have the opportunity to read that classic document and learn the truth about it.

"Later an advertisement enumerating the services given free by the medical profession in the City of Chicago and the fee table of the Chicago Medical Society will be given in full, with the qualifying statement that the

(Continued on page 814-adv. xxii)

tountains of refreshment

are just around the corner

Or ALL American institutions, none is more popular than the soda fountain. The sprightly cold drinks, the stimulating hot beverages, the ices, parfaits, sundaes and candies served there, not only bring refreshment, but their sugar content supplies the system with quick energy and nourishment without taxing the digestive system.

A famous athletic trainer always permits his men to eat all the ice cream they want. A well-known physician in Philadelphia often advises business men who are his patients to drop in at a soda fountain in the late afternoon and drink a flavored milk shake. Fatigue and

nervousness are overcome and dinner is eaten later with calm enjoyment.

This is one of the advertisements of the statements of the advertisements of the state of the statements in order to keep throughout the country, in order to keep throughout the country, in they been of the interest procedules they some of the medical practice, they have been of the medical practice, they have been of the medical practice, they have been of human mitted to and approved the field of human mitted to and approved the lield of human leading authorities in the United States.

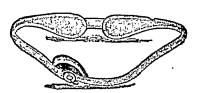

Such endorsement of sugar should not be overlooked. Too often home diets are lacking in this important food. The use of sugar may help in overcoming loss of appetite and in promoting indirectly a more balanced and varied diet.

For example, try a dash of sugar in cooking vegetables. It will heighten their flavor and cause them to be eaten with more relish. A dash of sugar also improves the taste of meats. The sugar blending with the salt and meat juices creates a delicious flavor. Good food promotes good health. The Sugar Institute.

Refresh yourself with a flavored drink"

BROOKLYN NEWARK

SPRINGFIELD BOSTON WILKES-BARRE CHICAGO

DETROIT-

(Continued from page 812-adv. xx)

members are ready and willing to care for the sick all of the time regardless of their financial condition.

"The next advertisement should contain an exposition of the money value of the services rendered by the medical profession without remuneration, based on the minimum fees of the fee table or a fraction thereof.

"In still another advertisement it could be admitted that the experience gained by caring for the sick paupers is of great benefit to the medical profession, but that the people able. to pay for medical services are the ultimate beneficiaries through the increased ability and experience of physicians. If the medical profession is not to be pauperized, those who can pay must bear the burden of the free medical service rendered, either by paying higher fees than they otherwise would have to pay, or by paying the physicians and surgeons for the services now donated.

"Further advertising should educate the public as to the truth about preventive medicine, dietetics, hygiene, and sanitation. Such a presentation of incontrovertible facts would serve to enlighten the general community as to the aims and ideals of the medical profession. It would for the first time enable the public to know the unbiased truth regarding its most valuable community asset, the ability of the capable medical profession to care for the health needs of the individual.

"However, it is admitted that no matter how truthful the copywriter, such articles if presented as free news notes or feature articles will be cut and garbled almost beyond recognition unless issued by those having the proper contacts or by the professional publicity men who also know better than the medical profession what the public will read, what is news, and what will be published widely by the press. In paid advertising the medical profession can tell the people what we believe they should know without having to defer to the city editor, without having to disguise items that are no longer new so that they may be treated as news.

"Finally, paid advertising makes it easier to get trustworthy free publicity.

"This is a formidable program, but it offers promise of excellent results. If carried out by an organization and on a high plane, with no exploitation of individuals or groups, no serious objection can be offered."

#### SECRETARIES' CONFERENCE IN INDIANA

The May issue of the Journal of the Indiana State Medical Association has the following description of a conference of the secretaries of the County Medical Societies of Indiana:

"Worthwhile, interesting, instructive, and a real party are the best words to describe the Annual Indiana County Medical Society Secretaries' Conference that was held at the American Medical Association headquarters, 535 North Dearborn Street, Chicago, Wednesday, April 23rd. Sixty-five secretaries, including a scattering of officers and councilors of the State Association, were present as guests of the American Medical Association.

"Following a morning's program of talks by the department and bureau heads of the American Medical Association, the entire group were luncheon guests of the A.M.A. at the Saint Claire Hotel. During the afternoon the visiting secretaries were divided in groups and a complete tour was made of the American Medical Association offices and building. All in all, it was very much worthwhile, and gave everyone present a clearer and more comprehensive idea of the enormous amount of work

that the American Medical Association and its 500 employees are doing for the medical profession of the country than could be obtained from any amount of reading. The secretaries saw the many workers of the various departments on the job and gained an idea of the many varied activities of the headquarters office.

omce.

"Just as soon as the motorbus arrived right on scheduled time at the A M.A. headquarters, carrying the twenty members of the "aero-squadron," the meeting got under way, the heads of the departments speaking in the following order:

"American Medical Association Headquarters,-W. C. Braun,

"The Council on Medical Education and Hospitals-N. P. Colwell.

"The Laboratory-P. N. Leech.

"The Bureau of Investigation-Arthur J. Cramp.

"The Council on Pharmacy and Chemistry—W. A. Puckner.

"Publications of the American Medical Association—Morris Fishbein.

AGAROL is the original mineral oil—agar-agar emulsion with phenolphthalein and has these

phenolphthalein and has these special advantages:
Perfectly homogenized and stable; pleasant tases without artificial flavoring freedom from sugar, alkalies and alcohol, no contraindications, no oil jesk-specin og griping or pain; no naurea or gaarte disturbances, not hable forming.

The second summer in the life of the child is popularly believed to be the most strenuous. There probably is something to it. As teething is at its height at this age period, digestive upsets may be expected. Many of them will be prevented if proper elimination is made a measure of precaution.

## AGAROL

the original mineral oil and agar-agar emulsion with phenolphthalein, is eminently suited for children because it contains no alkali, alcohol or sugar to interfere with the digestive processes. And Agarol is so palatable that children take it gladly.

Shall we send you two regular size bottles with our compliments? Send for them.

#### Tycos Pocket Type Sphygmomanometer

TWENTY-TWO years ago the first Tycor Sphygmomanometer was placed on the market Although modifications have been made whenever desirable, fundamentally the instrument remains the same today.

Every Tycos Sphygmomanometer has adhered to an indisputable principle—that only a diaphragm-type instrument is competent for the determination of blood pressure. To faithfully record the correct systolic pressure, an indicator's accuracy must not be affected by the speed at which the armlet pressure is released, only a diaphragm instrument can guarantee this. To honestly give the true diastolic pressure, a sphygmomanometer must respond precisely to the actual movements of the arterial wall, again, only a diaphragm instrument can do this. Portable, the entire appartus in its handsome leather case is carried in coat pocket. Durable its reliability in constant use has been proved by many thousands of instruments during the past twenty-two years. Accurate, its precision is assured by relation of the hand to the oval zero. Further information relative to the Tycos Pocket Type Sphygmomanometer will be furnished upon request.

Write for new 1930 edition of Tycos Bulletin No 6 "Blood Pressure-Selected Abstracts" A great aid to the doctor who wishes to keep abreast of blood pressure diagnosis and technique.

"Enucleation of eye and subsequent care, \$50.00, \$125.00 with implantation."

#### LAW ENFORCEMENT IN KENTUCKY

The prosecution of illegal practitioners of medicine in Kentucky seems to fall upon the physicians of the State. Light is thrown upon the Kentucky procedure by the following editorial from the June issue of the Kentucky Medical Journal:

"From several sections of the State rather vitriolic complaints have been received at the offices of the Association because some quack, or patent medicine vender, has appeared in the county and has not been prosecuted by the Association.

"Physicians must understand that laws do not enforce themselves. Legal evidence of violation must be secured and it can only be secured locally. Under our system of local self-government, which has long been the pride of the State, the local authorities have charge of prosecution for crime. Under the Medical Practice Act, the local Boards of Health are charged with the responsibility of the arrest and trial of violators of the law. The County Attorney is, by law, required to prosecute the cases in the courts. The State Association and the State Board of Health together, for the past several years, have employed special council to assist the County Attorneys in these prosecutions. For each of the past four years between three hundred and four hundred convictions have been secured. In the very nature of the cases the State officers cannot know about these violations and cannot find the witnesses, although they are common knowledge to the people of the locality in which they occur. We are ready to help any community that needs us.

"There is another phase of the matter that the physicians of the counties are entirely responsible for. Some Circuit and County Judges, some Commonwealth and County Attorneys, refuse point-blank to enforce the Medical Practice Act. Such men should be defeated at the polls, and can be, whenever the profession exercises its powerful influence in this respect. Any law can be enforced if the officers elected for the purpose do their duty. If any fail to do it their successors should be

of a different type."

#### POST-GRADUATE COURSES IN GEORGIA

The following article in the May number of the Medical Association of Georgia describes the post-graduate courses sponsored by the State Society:

"At the 1929 session of the Medical Association of Georgia the House of Delegates directed its Committee on Scientific Work to cooperate with the State Board of Health, the Extension Division of the University of Georgia, Emory University School of Medicine and the Medical Department of the University of Georgia to arrange for courses in

post-graduate study.

"At a meeting of representatives from these bodies, Mr. J. C. Wardlaw, Director of ex-tension work at the University of Georgia was appointed chairman of a sub-committee to work out in detail the proposed courses of study. After overcoming many difficulties, these courses were planned for six leading cities in the State. On account of his unavoidable ab-sence Mr. Wardlaw was unable to give his report to the House of Delegates at the recent Augusta session. However, it was read by the Secretary-Treasurer.

"The committee has arranged for postgraduate courses at Cordele, Bainbridge, Rome, LaGrange, Waycross, and Cornelia. At each of these cities the program which follows

will be carried out.

"Notices will be mailed to all physicians contingent to these cities in ample time for them to learn of the definite hour and place of meetings."

#### OUTLINES OF LECTURES

"Monday-Diagnosis and Care of the Tu-berculous-Dr. E. W. Glidden, Superintendent State Tuberculosis Sanitarium,

"Mental Hygiene-Mr. Austin E. Edwards, Professor of Psychiatry, University of Georgia. "Tuesday-Diseases of Children-Dr. W. A. Mulherin, Professor of Pediatrics, University

of Georgia,

"Wednesday-Pneumonia, Chronic Abdominal Conditions, Diabetes Mellitus-Dr. Cyrus W. Strickler, Professor of Medicine, Emory University.

LARGE HOMESTEAD, exceptionally suitable for school, sanatorium or home, 18 rooms, 5 baths, 12 acres ground, large barn, stable, nine stalls, room for four cars, with four-room and bath apartment above; about 600 feet elevation, about 25 miles from New York, Lackawanna Railroad. Buildings, grounds, perfect condition. Price \$75,000—part cash, suitable mortgage. Address Box 140, care N. Y. State Journal of Medicine.

### AN ADVANCE IN CARDIAC THERAPY

Whatever improves our means of combating heart disease becomes of paramount importance. Really efficient cardiac remedies are few in number. Digitalis has hitherto stood in a class by itself. Everyone acknowledges its tremendous value, but when it fails—there hardly is anything to take its place. This is what gives great significance to the acceptance of Scillaren "Sandoz" by the Council on Pharmacy and Chemistry of the A.M.A., on May 31, 1930.

Scillaren, the active principle of squill, slows the rhythm and augments the amplitude of the heart beat. It brings about a more efficient systole and a longer diastole, thus resting the heart and improving the circulation. It increases the urinary output and often succeeds when other diuretics have failed. It is less cumulative than digitalis and less liable to cause nausea and vomiting than other cardiac remedies. These features make it especially valuable in cases refractory or intolerant to digitalis, and particularly suitable for long continued administration.

Scillaren comes in tablets and solution for oral administration and in ampuled solution (Scillaren-B) for intravenous injection when immediate response is needed. See page xiii—Adv.

#### "YOU ARE ALWAYS THINK-ING OF THE DOCTOR'S VIEWPOINT"

This was an expression frequently voiced at the *Mead Johnson* exhibit at the recent A.M.A. session. The unique showing of ancient feeding spoons and nursing bottles was the special attraction this year.

At a previous exhibit, the feature was a motion picture of the cod liver oil industry as related to the doctor's interest in vitamins A and D.

A few years ago, when the breast pump was new, Mead Johnson & Company demonstrated one of these useful devices. "What?" exclaimed many doctors, "You make infant diet materials, and yet you demonstrate something that promotes breast feeding and destroys your own business?"

Then we explained that from the beginning, we recognized the superiority of breast feeding, that it was we who coined the slogan "First Thought Mother's Milk, Second Thought Dextri-Maltose, Cow's Milk and Water."

tri-Maltose, Cow's Milk and Water."
Invariably the reply was, "You have the right idea. See page xv—Adv.

## LARGE HOMESTEAD, exceptionally suitable for school, sanatorium or home, 18 rooms, 5 baths, 12 acres ground, large barn, stable, nine PHYSICIANS' DIETARY PROGRAM

A problem that frequently confronts the physician in prescribing a dietary program for increasing the mineral salt and vitamin content in food, in a corrective or preventative treatment, is how he may insure its being carried out, so that the patient will receive the desired benefits

The taste of certain most desirable foods such as spinach, carrots and onions is attractive to the patient if a proper method of preparation is used. This makes possible the maintaining of a more correct balance of nourishment. To aid in accomplishing this, a new kind of service for the busy practitioner has been established by the Institute of Applied Cookery at 409 Amsterdam Avenue (between W. 79th and 80th Sts.), New York City. Patients may be referred to this Institute with every confidence. A competent staff of experts is prepared to show patient or householder (either here or in the home) how to preserve the natural food flavor and to minimize the loss of important food factors.

This Institute is not concerned with any dietary program of its own but to carry out the physician's instructions. It can furnish, when necessary, the desired equipment for home use which is truly scientific yet entirely practical. The method involves the Dry Cooking of most vegetables, etc., in practical vacuums at low temperatures. Minimum oxidation is insured with only atmospheric pressure. In most instances, only the condensation of the natural moisture of the food is used in the cooking process. The Profession is cordially invited to write for further information, or to telephone (Susquehanna 7709) for appointments for patients or to have our representative call. See back cover.-Adv.

#### GRAPE JUICE

The Dewey Company at its plant in Egg Harbor City, New Jersey, makes a cool process grape juice from grapes grown on the rich soil of southern Jersey.

The same Grape Juice is combined by the Dewey Company with Mineral Oil and Agar-Agar (known as Grape Minol). Although it is a recent combination it is stocked by all of the New York jobbers, and can be secured by the physician from his druggist.

The Dewey Company will gladly send samples of either Grape Juice or Grape Minol to the physician upon request. See front cover—Adv.

A' well known Urological Journal says:

"If you must use a diuretic, try the best —water"

This recommendation is well worthy of adoption especially if

## )foland Water

is used. ¶ Physicians have commented favorably on its bland diuretic properties for over 60 years.

#### CANCER CONTROL IN OKLAHOMA

The report of the Committee on Cancer Study and Control in Oklahoma is contained in the May issue of the Journal of the Oklahoma State Medical Association which says:

"We have not attempted any major activity during the year though have not been entirely idle since our last meeting. We have durectly or indirectly been responsible for numerous programs featuring cancer and have distributed several hundred pamphlets furnished by the American Society for the Control of Cancer. There have been numerous addresses upon the subject of cancer given before both public and medical audiences.

"Through the courtesy of the American Society for the Control of Cancer, we have been privileged to book for a period of two weeks the wonderful 'Dr. Canti Three-Reel Cancer Film.' At the time of this writing, our program has been outlined and dates given for the showing of this film before joint meetings of county medical in different localities societies which will cover the larger portion of our State. The program begins with the exhibition of the film at Chickasha, April 8th, and ends at Oklahoma City, April 19th.

"Physicians everywhere have shown an increasing interest in and have become more anxious to obtain knowledge upon the subject of cancer. The public has also manifested even a greater interest in certain localities than physicians, due no doubt, to the wide newspaper publicity of the experimental work upon cancer which has been announced from some two or three different research laboratories within the past eight months. These reports have been carried frequently and extensively by the Associated Press. Perhaps a larger space has been devoted to the discussion of cancer by the public press during the past year than in any previous year in which cancer education has been undertaken."

## Cystitis Orchi-epididymitis Prostatitis Urinose Abscesses

and in all acute or chronic Inflammatory Processes of the Genito-Urinary System

## Antiphlogistine

due to its stimulating and regenerative action, hastens repair, relieves swelling, reduces pain and is an efficient factor in the treatment.

Antiphlogistine possesses sedative and antiseptic properties, in addition to its ability to produce osmotic lavage, which is the mechanical phenomenon taking place in a membrane separated by two fluids of different molecular concentration.

"Osmotic lavage is far more beneficial than the superficial lavages, which never penetrate the membrane and merely produce a surface reaction."

(E. Doumer, of the French Academy of Sciences.)

## A Dependable Agent For Supplying Calcium In Diffusible Form

KALAK WATER presents a saturated solution of calcium as the bicarbonate.

"Of the inorganic salts of calcium, the bicarbonate was the most effective in raising the blood calcium." (W. H. Jansen-Deut. Arch. I. klin Med. Oct. 1924.)

It is not possible to present esterior blessbonate as a dry powder or as an efferessent mixture to be added to water. This salt can be maintained as the blessbonate only in an aqueous solution that is charged with estbon closible.

KALAK WATER CO. 5 Church St. ... New York City

## A FOOD WHICH STOPS

## Intestinal Putrefaction

THE presence of colon poisons from intestinal putrefaction is an abnormal and a serious condition which saps the vitality and is the root cause of a variety of functional disorders.

Fortunately it is possible to prevent the development of putrefactive germs and other poisonous products by changing the intestinal flora.

The perfection of the food product-

#### Lacto-Dextrin

provides the special carbohydrate combination which affords a rational and effective method of promoting the growth of normal friendly germs in the intestine—the antiputrefactive organisms, B. acidophilus and bifidus.

Sometimes, in obstinate cases, quicker results can be obtained by combining Lacto-Dextrin with Psylla seeds (plantago psyllium). The latter supplies bulk and lubrication and so combats constipation and hastens the passage of Lacto-Dextrin into the colon.

You will find the story of how to use Lacto-Dextrin and Psylla highly interesting as it is told in the book, "The Intestinal Flora." We shall be glad to send you a copy together with clinical trial packages.

The coupon is for your convenience.

## NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

Vol. 30, No. 12

NEW YORK, N. Y.

June 15, 1930

#### A VISION OF THE FUTURE OF MEDICINE

By WILLIAM H. ROSS, M.D., BRENTWOOD, N. Y.

The President's Inaugural Address before the Anniversary Meeting of the Medical Society of the State of New York in the Hotel Seneca, Rochester, N. Y., on the evening of June third, 1930.

A year ago in accepting the office of President-Elect, I believed that I understood the responsibility that I would have to assume a year hence. I thought that this was true because of the opportunity that I had had to observe the activities of organized medicine; but contact with forty-five groups of physicians as well as with many official and unofficial agencies and officers of the State Government and discussion with them of the problems of the profession, have brought into a much clearer perspective the burden of responsibility that goes with informed and adequate leadership.

The present public character of medicine, the increased economic capacity of the public, and a year's study of the social trends in this country have brought into clearer perspective, also, the real problem confronting the medical profession and with it the need for a new relationship and a new adjustment of interest in health activities that have come to command so large a measure of public interest and even governmental support.

A workable, cooperative relationship between the profession of medicine and health agencies is approaching; the aim is a mutual understanding of the objectives of these organizations and a mutual respect for their differences Just as soon as the principle of conference is established as a method of arriving at an understanding of the value of coordination of all health efforts, the profession will have taken a long step toward solving its economic problems.

The changing economic relationship in every field of human endeavor includes, of course, the practice of medicine. The full development of the beginning era of preventive medicine will mean more economically as time goes on unless physicians adopt preventive practice. This means a new conception of medical practice but it is nothing more than the addition of preventive methods to a physician's regular work.

If a patient calls to see a doctor with a severalpage report from the Life Extension Institute or some group clinic, and he sees upon looking it over that he could have done the same thing if he were a little better equipped and that he could have earned the fee that his patient paid elsewhere, it will stimulate his interest in preventive work as much as anything else will do. Should his patient inquire why he has never suggested a health examination, what would his answer have to be?

Just as advancement in the relationship of industry comes primarily from confidence, advancement in the relationship of medicine will come from confidence Confidence develops only from a coordination of understanding of the purpose of an organization—no matter what kind

Medicine is organized for just two essential purposes—the advancement of its science and the betterment of public health. The advancement of its science has now such momentum that it requires comparatively little effort to keep it going. The other great objective of organized medicine, the betterment of public health, needs closer study and more definite support.

There is now an effort on the part of many organizations to carry health more efficiently to the public. Examples like the toxin-antitoxin work of the five counties in the Metropolitan District last year could be given from personal observation in other parts of the state and in other states if there were time.

There is now going on a rapidly advancing adjustment of professional relationships. Conservatism is relaxing enough for this adjustment. The value of tradition is being weighed. Ethical conceptions are being modified enough to include the advising of the public by physicians themselves to accept preventive medicine at the hands of the practicing physician. Even the teaching of the medical schools has made advances in developing in their students an understanding of the social aspects of medicine, and they are now infiltrating their teaching of curative medicine with the methods of prevention of disease.

The Medical Society of the State of New York has undertaken to establish a cooperative rela-

tionship with health organizations, and with the State itself in every health program. It has suggested to the medical profession a readjustment of its relation to the obvious trends in public interest, and it has been met more than half way by every organization and by every department of government of this state with which it has conferred. It is apparent that the health organizations and officials of the state government desire to have the medical profession take the leadership in health matters, and the doctor to become again the leading spirit in the health of his community. The public and all health organizations will follow the leadership of the profession if the profession will show the way.

It is an accepted thesis in industry that an organization should function to its capacity before added equipment is installed. We are not yet operating our organization to capacity. It is an accepted essential in all industrial organizations that there shall be a certain continuity of personnel which should change slowly, and only for the purpose of training new men so that knowledge of past experience shall be preserved for success in new fields. The same thing should be applied no less definitely in medical organization.

There should be a close cooperation between the heads of Standing Committees because the work of each committee has a bearing upon the work of all other committees. The Standing Committees of the State Society have an interdependence and are not separate organizations. They could with value come together in more frequent conference.

The duties of the President of the State Society have come to be so many that they demand almost all of his time. His burden is heavier year by year with the complexity of official duties. Medical progress, public interest, public demand, the public character of medicine,-all these bring problems that will increase rather than diminish. Recall the days when a President's duties consisted of meeting a few committees once or twice, and presenting at the annual meeting a thesis on some subject of his own choosing. Then compare them with the work of any one of the Standing Committees today. Each of the Standing Committees is doing more constructive work today than the entire Society did a comparatively few years ago. Two of these Committees-Graduate Education, and Public Relations—are less than six years old. President's duties are further increased by the need of informed and adequate understanding of the work of every committee, if he is going to meet his responsibility and the obligation assumed in accepting the office. There is an increasing demand for the President to attend medical meetings, and he ought to meet this demand in order to interpret the ideals of medicine to these groups.

One of the outstanding problems, the readjustment of the medical profession to social needs, is actually in process of solution by Dr. Sadlier's Committee on Public Relations. The ideal that inspires this effort is that professional service should be coordinated with all other services in health. The modern county health department and the relation of the profession to the state-aided county hospitals are illustrations of the work of this committee.

Another outstanding problem is actually in process of solution by Dr. Farmer's Committee on Graduate Education. Its ideal is the reinstatement of the family doctor in public estimation, which can best be done by making him a better doctor. The practical need for this is that the future of preventive medicine really depends upon the family doctor. Could we measure the result if we had graduate education at regular intervals for all of the profession? Would not the leadership of the American medical profession in the betterment of public health be established on as sound a basis as Denmark's, for example, by the reinstatement of the family doctor, the initiation by the profession of better public health administration, the coordination of all health services, and consistent graduate education? Would not these things put us in position to solve almost all our important problems?

Meeting physicians this year has increased my pride in medical men. The desire to elevate the standards of practice and the ideals of service are as great in one place as another. Sometimes, however, one hears a discordant note. I have heard, "What has the State Society done for me?" and "I do not like the way they run things in the State Society." On one occasion I was able to reply that all laws and regulations, standards of practice and professional education, and "many of our privileges" would not be here except for organized medicine. On another occasion I was able to say, "Well, then, come on in and help change things." If one has not taken the trouble to make suggestions or to take part in the activities of the State Society, the Society is deprived of his assistance.

Medical organization grows better year by year. It is doing many things to make professional life better, and is steadily advancing the interpretation of medicine to the public. The future of medicine is brighter than ever before. The real problem is a matter of modernizing relationships and expanding graduate education. Recognition of the changes that are going on in the world will help us to understand the social aspects of the modern demand for health service; it will help us to understand why all mankind has changed its front toward disease; it will lift us out of the conception that the practice of medicine is only curing disease after it has commenced, into the newer conception that many

diseases can be prevented and many more modified. Little does the profession seem to understand its dormant power, the power of unanimous opin ion as laymen understand it. Organized medicine should realize its latent influence on all public health questions and should recognize the reflex value of leadership on its own reputation.

While we do not believe that a minority should over control, a minority must apparently forever hold aloft the torch of the ideals of medicine as a minority has always done in other fields of human effort

Washington was once in the minority at Valley Forge

Lincoln was in the minority after the Battle of Bull Run

Andrew Johnson was in the minority in upholding the Constitution in 1866

We are in the midst of world changes of tre

We are in the midst of world changes of tre

The ethics of husiness no more than two decades old and the economic relationships of industry have changed by leaps and bounds

Protection of the public by rules of conduct has advanced beyond the professions

Education has grown beyond the conception that anyone had a few years ago

Public opinion is demanding the control of disease as far as known

The door of opportunity for the medical profession to advance public health by prevention of disease and to strengthen its leadership, has opened in line with other world changes

#### **OBSERVATIONS ON AGRANULOCYTOSIS\***

By NATHAN ROSENTHAL, MD, NEW YORK, NY

From the Melical Defartment and Laboratories Mt Smai Hospital New York A Y

AGRANULOCYTOSIS is the name applied by Schultz' in 1922, to a symptom complex which is characterized by necrotic manifestations in the mouth and throat and profound diminution in the number of white blood cells, affecting mainly the polymorphonuclear cells According to the first reports of this investigator? the main features of this unusual condition are

- 1 Sudden onset with high fever and general malaise
- 2 Ulcerations, necroses, diphtheritic or gangrenous processes, especially of the tonsils, pillars of the fauces, uvula, palate and pharying and, occasionally, similar lesions of the gums, tongue, larying and gentals
  - 3 Absence of hemorrhagic diathesis
  - 4 Presence of icterus
- 5 Occasional enlargement of the liver and spleen
- 6 Characteristic blood picture There is profound depression of the white cell count—usually less than 1,000 with disappearance of the polymorphonuclear leucocytes. The red cells and blood platelets are not disturbed
  - 7 Rapid fatal course

Schultz<sup>2</sup>, however has lately modified his opinion and is now inclined to accept cases which do not show jaundice, and even some in which anemia is present. Recoveries have been noted by him in four cases. It is not necessarily a fatal disease, as 13 per cent of cases recover.

The first case of this symptom complex—now

\*Read at the Annual Meet no of the Medical Society of the State of New York at Uties N Y June 6 1929

designated as "Agranulocytosis" or "Agranulocy tic Angina"-was reported in this country in 1902, by Brown' as "A Fatal Case of Acute Pri mary Pharyngitis with Extreme Leukopenia" The patient, a married woman 29 years of age, compluned of fever and chilly sensations following exposure to cold On the following day her throat was a little sore and on examination, the tonsils were found to be swollen and red The spleen and had no pain on swallowing peripheral lymph nodes were slightly enlarged Blood examination on the second day revealed the following findings hemoglobin 65 per cent, red blood cells, 3,240,000, white blood cells 1,000 Differential count; polymorphonuclears 1 per cent, lymphocytes 99 per cent. On the third day there were 400 leukocytes, and on the fourth day 320 The swelling of the tonsils and neighboring parts increased slowly and pain on swallowing became intense. This applied particularly to the right tonsillar region. An incision was made but no pus was obtained. A membrane formed over the cut which persisted until death, the latter occurring on the seventh day of the disease The number of leukocytes on the sixth dry was reduced to 260, with a differential count of my clocy tes 2 per cent, polymorphonuclears 21 per cent, and lymphocytes 77 per cent

The second case of this condition was described by Turk, in 1907, but the real identity and characteristics of the disease were first reported by Schultz His criteria, however, had to be modified as more cases were reported

Kasthn<sup>5</sup> analyzed the findings in the first 43 cases and in two additional cases. Lauter<sup>6</sup> was the first to report a case resulting in recovery. Rotter<sup>7</sup> was the first to publish a case in a male

patient. Wyatt<sup>8</sup> called attention to 47 other cases in the literature and reported one of a woman, aged 43, who made a complete spontaneous recovery. Recently, Rose and Houser<sup>o</sup> have again reviewed the subject from the standpoint of its infectious nature, and have come to the conclusion that it is not a disease entity. Their report is based on a fatal case of pneumococcus sepsis and agranulocytosis. In all 180 cases have so far been reported including 10 cases observed by the writer.

Other terms have also been applied to this symptom complex but the most preferable still takes its name from the outstanding symptom, The following names namely, agranulocytosis. have also been used for the condition: agranulocytic angina (Friedemann), stomatitis myelophthisica (Jagič and Spengler), malignant leukopenia (Pelnar), mucositis necroticans agranulocytotica (Weiss), agranulocytic infection (Rose and Houser).

#### Symptomatology

The onset is usually sudden, but occasionally there is a previous history of long-continued ill health, or of sore throat or influenza-like attacks; the patient complains of dysphagia, sore throat or dyspnea; the voice becomes rather peculiar, resembling the so-called "hot potato" type of peritonsillar abscess. Prostration is intense and is frequently out of proportion to the extent of the lesions present in the throat. In a few of the cases observed, the angina was absent. The jaundice which was first thought by Schultz to be present in all cases, occurs in less than 50 per cent; it is sometimes terminal.

Physical examination reveals ulcerations and necroses of the tonsils; similar lesions may appear in the pharynx, pillars, uvula, hard or soft palate, tongue, gums. A few cases without ulcerative lesions have been reported. The cervical nodes are usually enlarged; an edema may appear below the jaw or on one side of the neck. In one of our cases (Case 4) a terminal gas infection was present on one side of the neck. Hemorrhages from the ulcerated areas rarely occur; the liver and spleen may be palpable; ulcerations similar to those appearing in the mouth may be observed in the anal region, vulva, and vagina. Various types of skin lesion have been described, such as erythema, herpes, maculopapular eruptions, which may occur in any form of toxemia or septicemia... The urine shows the presence of albumin; urobilin and bile are present in jaundiced patients.

#### BLOOD PICTURE

Agranulocytosis assumes the aspect of an infectious disease with a characteristic blood pic-The hemoglobin and red blood cells are usually normal and may become somewhat subnormal during the course of the disease. most important feature of the blood picture, how-

ever, is the extreme leukopenia. This varies from 100 to 5,000 white blood cells.

The differential count shows a disappearance of the polymorphonuclear neutrophils or a great diminution of their number. There is also a decrease in the lymphocyte count. The plasma cells and monocytes may be increased. Macrophages and even myeloblasts may be found. The blood platelets are either normal in number or somewhat increased. In one of our cases (Case 4) there was a diminution of the blood platelets as the disease progressed.

In favorable cases there is a prompt improvement of the blood picture. The young polymorphonuclear cells (staff cells) appear when the leukocyte count begins to increase. The granules of the staff cells show peculiar staining reactions; the granules stain rather dark and coarse. Later the normal neutrophilic granules appear and also mature segmented polymorphonuclears.

#### BLOOD CULTURES

In a number of cases of agranulocytosis the blood culture has been found to be positive. Different types of organisms have been found, so that one cannot consider this a specific infectious disease. Of all the cases so far studied, a positive blood culture was obtained in 28 of 75 cases. The various organisms found are the following:

Streptococcus hemolyticus, 7 cases.

Pneumococcus, 7 cases. Staphylococcus aureus, 5 cases.

Bacillus coli, 2 cases.

Friedländer bacillus, 2 cases.

Streptococcus viridans, 2 cases.

Streptococcus hemolyticus and Staphylococcus aureus, 2 cases.

Streptococcus hemolyticus and Bacillus coli,

In the writer's series (Table I) 4 cases out of 7 had a positive blood culture, which indicates a had prognosis.

#### Age and Sex

The preponderance of agranulocytosis in middle-aged women, previously in apparently good health, is a rather striking feature of the condition, only 24 cases having been reported in males up to the present time. This disease is rarely seen in persons under twenty years of age. A few cases have been reported in children.

CLASSIFICATION OF AGRANULOCYTOSIS BASED ON OBSERVATIONS OF TEN CASES (TABLE I.)

Group I. Agranulocytosis with fatal termination (4 cases).

Group II. Aleukocytic Angina (1 case). Group III. Agranulocytosis followed by re-

covery (4 cases).

Group IV. Agranulocytosis, recovery followed by persistent agranulocytosis (1 case).

All of the above cases, which will be reported

TABLE I

GROUP	Case	Sex	Age	ULCERATIONS	BLOOD CULTURE	WHITE CELLS	Polys	LYMPHS	Result
1	1. E. M	F.	33	Throat Rectum	Streptococcus Hemolyticus and Bacillus Coli	600	0	95	Died
,	2. M. M	F.	48	Throat	Staphylococcus Aureus	200	0	98	Died
	3. A. R	F.	60	Throat	Streptococcus Hemolyticus	500	0	85	Died
	4. E. M	F.	28	Throat	Streptococcus Viridans	250	0	100	Died

Classification of Agranulocytosis Based on Observations of Ten Cases (Table I.)

in detail later, had the two main characteristic manifestations of agranulocytosis, namely: the leukopenia and the septic manifestations. Only one case did not show any angina, which has previously been observed in a few cases. The data in the table are self-explanatory.

It is important to note that the fatal cases have a complete absence of polynuclear cells and leucocyte count below 1,000. The prognosis is favorable in cases with a negative blood culture and leucocyte count above 1,000.

The differential diagnosis offers no difficulties, provided one is aware that secondary agranulocytosis and ulcerative manifestations may be a terminal complication of aplastic anemia, leukemia (myeloid and lymphoid), Hodgkin's Disease, Jaffe¹, Miller¹¹, possibly as a result of previous radiotherapy. Agranulocytosis may result from neosalvarsan and benzol poisoning and may follow x-ray and radium treatment. In this communication we are dealing with true cases of agranulocytosis, or Werner Schultz' disease (Chevallier)¹².

#### ETIOLOGY AND PATHOGENESIS

Many views have been expressed in regard to the cause of this condition. From the summaries by Schultz, Hueper, 18 Rose and Houser, we may gather the following ideas as to the

- 1. The condition is a specific disease entity.
- 2. It is a granulo-leukopoietic disease of the bone marrow.
- Some specific selective toxic action of the bone marrow is present, making the body less resistant to secondary invasion of bacteria.
- The condition is due to an infection on a pre-existing hypoplasia of the granulopoietic apparatus.
- It is a maglignant leukopenia of leukemic nature.
- 6. It is secondary to some endocrine influence.
- 7. Atypical form of sepsis.

Due to the fact that the condition is not a common one, most of these views were apparently expressed after studying comparatively few cases. The present writer is rather inclined to accept part of Schultz's and Friedemann's views on the nature of this condition. Even these investigators have changed their views occasionally. Schultz recently suggested that there is possibly a toxic action of some virus which has a special affinity for the myeloid system. However, from the study of ten cases and observations on a few other cases, the writer is finclined to the view that agranulocytosis is a clinical chiral chiral related to a constitutional hypophyly of

the leukopoietic system; in other cases it may be a result of transitory hypoplasia. One cannot say definitely that in the latter group this hypoplasia is due to endocrine influences. The septic manifestations are of a secondary nature and produce pathological lesions which are common to septic conditions without the inflammatory reaction. The prognosis of the case depends upon the extent of the invasion of the bacteria. The bone marrow may recover before the septic manifestations have gone too far. In five of our cases which recovered, it seemed that the healing of the ulcerations started about the time the polynuclear leu'tocytes began to show definite increases in the blood.

The marked diminution of the polynuclear cells removes the great defensive mechanism, thus rendering the body less resistant and subject to rapidly spreading infections. These infections begin only in areas where numerous organisms are constantly present. The most common of the septic manifestations are, naturally, the tonsils: the gums; tongue; and other areas of the mouth may also show ulcerations. In some cases, the ulcerations of the mouth may be absent. Recently, the writer in consultation with Dr. Jaffin of lersey City, had occasion to observe a case in a young woman who had all the symptoms of agranulocytosis, including a marked leukopenia of 800 leukocytes. There were no throat manifestations whatsoever, and after a thorough examination of the patient only a gangrenous necrosis of the rectum was accidently found on proctoscopy. Following a transfusion, the patient made a rapid recovery.

The bone marrow, therefore, must be considered an organ which is subject to hypoplasias and hyperplasias of various kinds, similar to hypoplasia or hyperplasia of the thyroid gland or the other organs. As various elements are present in the bone marrow, variations in hypoplastic changes may be anticipated. The bone marrow is composed of formative areas or red cells, white cells and blood platelets, so that we can expect to obtain various forms of hypoplasias. Agranulocytosis may be considered a condition resulting from an aplasia or functional disturbance of the leukopoietic system, similar to certain forms of thrombocytopenic purpura.

Hypoplasia of the leukopoietic apparatus lead to a leukopenia. This may be secondary, as in certain types of infections which actually involve the bone marrow (typhoid fever), (tuberculosis, Hodgkin's disease), or due to influences of certain organs, as the spleen and liver. Leukopenia may also result from the removal of leukocytes from the blood, as in Gaucher's disease, Banti's disease, hemolytic icterus. There is also a constitutional hypoplasia of the bone marrow which may result

in a persistent leukopenia. Case 10, reported in this paper is an example of this condition. This man is apparently well, and his blood picture always showed a leukopenia without anemia or thrombocytopenia for four years following the first observation.

#### TREATMENT

There is no specific treatment for this disease. The most important procedures employed for the purpose of hastening recovery are: transfusions and intravenous injections of neosalvarsan. Mild irradiation of the long bones has apparently produced satisfactory results in some cases. However, in two of the author's cases, and in some cases reported in literature, irradiation did not produce any immediate effect. Most of the cases recovered spontaneously.

#### Prognosis

Thirteen per cent of the cases have recovered. It is rather unusual that 50% of the cases observed by the writer, recovered (five cases out of ten).

Conclusions

- 1. Ten cases of agranulocytosis were observed with a mortality of 50 per cent. Two additional cases have been seen in consultation, which have recovered. Another case is known to have recovered from an attack twelve years ago.
- 2. The disease is a symptom-complex with two phases. One is a localized ulcerative condition of the Waldeyer ring (tonsils, pharynx, pillars of the fauces, tongue, etc.), accompanied by symptoms of sepsis. The second phase is an associated profound leukopenia affecting mainly the polynuclear neutrophils.
- 3. The leukopenia is possibly due primarily to a functional disturbance or a hypoplasia of the leukopoietic system; septic manifestations are probably secondary as a result of the absence of the leucocytic defensive mechanism of the body.
- 4. Hypoplasia of the bone marrow may be transitory or it may possibly be a permanent constitutional disturbance as in cases 5 and 10. Such patients are predisposed to the development of agranulocytosis.
- 5. Recovery is usually spontaneous, following re-establishment of the function of the bone marrow, provided the septic invasion is not too extensive.
  - 6. There is no specific treatment.

#### MEDICAL ACCOUNTING IN COMMUNICABLE DISEASES\*

By HENRY JAMES SPENCER, M.D., NEW YORK, N. Y.

BY medical accounting I mean the computapital and other practice I propose to show you how study or analysis of such accounting has proven of great value in improving our service to those suffering from communicable disease

The man in almost any activity who knows exactly how his affairs stand has an advantage over the one who has a notion about it but no real ac The solid foundations of medicumulated facts cine are built on experiments or clinical observations which were carefully planned, later analyzed and then reobserved in the light of the new concepts formed

When we apply the idea of accounting to a general hospital service so many ramifications are found that one is liable to be confused. But in a communicable disease hospital the problems are knit together to form a compact whole Moreover there is a greater urge for accounting because of the very communicability of the conditions dealt with

The urge in our case, at the Willard Parker Hospital, was and is the saving of children's lives and health The mortality of 1922, chiefly due to We had, theretofore, measles, left us aghast taken our responsibility like a man with notions Suddenly we were like a man who, having kept no books, found himself bankrupt Certain things were obvious when we looked about. We made changes We set an ideal. That ideal was to save for patients; first, their lives, second, their bodily functions and health and finally unneces sary days of illness and confinement

That has proven no mean problem established medical aseptic technic. Next cubicles were erected in all open wards. Soon we realized more fully than ever that we must not trust to notions and so our monthly statistics were established Most of the credit must be given to Dr Shirley W Wynne, then Director of Hospitals of the Health Department and now Commissioner of Health of the City of New York and to Dr Arthur W Bingham, then President of the Medical Board who later gave up his life largely be cause of his efforts in pushing toward the ideal

The statistics have grown and changed have upset some of our notions, supported others and also have given us some entirely new concep-We are not sure that the present method of accounting is the best. We are as ready to take up and try a new method of accounting as we are to follow out the leads that our present method gives us

When men think through to their ends the problems which arise from such an accounting certain needs become evident and if men are earnest and zealous in seeking to have these ends met they are very likely to be misinterpreted. They must support their thinking with facts. No, even more, their facts must be so fully divorced from personal bias that they stand by themselves

The needs that appear are surprisingly many They are not limited to the development of newer and better methods of treatment though such things do come out of them. But they deal with food adequate nursing and medical care, proper sterilization of bedding, crowding in the admitting rooms, urging of the earlier calling of the family doctor, training of the family doctor by means of climes so that he will correctly diagnose diseases earlier and more adequately treat his patients These are samples of what our statistics have lead us to

The aseptic technic was started late in 1924 so that statistically 1925 should be considered the first year 10,777 cases were treated from 1922 to 1924 inclusive with a mortality rate of 12.8% From 1925 to 1928 inclusive 14,891 cases were treated with a mortality rate of 826% IIad the 1922 1924 mortality rate held for these later years 1,906 persons would have died instead of 1,230,

a saving of 676 lives in four years

What share of the deaths must the Medical Staff consider as reflecting the care and skill shown in the hospital? We have assumed that deaths occurring within 48 hours after admission are largely unavoidable as far as we are concerned if they receive prompt, intelligent care record all deaths as occurring within or over 48 hours after admission Of the deaths occurring over 48 hours after admission, a large number, particularly of measles and diphtheria cases, by great effort are tided over the 48 hours only to die later Allowing for these, the percentages of nortality for the "over 48 hour" cases are of considerable significance for purposes of com-DIFISOR

<sup>\*</sup>Read at the Annual Meeting of the Medical Society of the State of New York at Utica N Y June 5 1929

TABLE I

	1922	1923	1924	1925	1926	1927	1928

Difference—Lives Saved						58	8

The only figure which we would pretend was in any way due to our efforts is the saving of 588 lives in the "over 48 hour" group. These figures must not be accredited to the aseptic technic alone. Aside from the technic better and more abundant nursing care, less fatal complications, fewer cross infections and the like must be

taken into account. However, the reorganization of the medical and nursing service which included starting the aseptic technic, played an important part.

When the diphtheria, scarlet fever and measles admissions and deaths are studied separately interesting details again appear.

sive (49 (1.5%) B.A. and 82 (24%) A.A.). The integrity and faithfulness of the professional staff were questioned 52 of these 131 cross infections were with measles and 60 with varicella, accounting for 112 of the 131 cases. This occurred in a year when measles was not present in the city in epidemic proportions, though varicella was We believe the source of the trouble was discovered when it was found that the large autoclave for the sterilization of bedding was ineffective

ling measles and chicken-pox as causes of longer hospitalization and hence greater cost to the community.

The pathological department of a communicable disease hospital is where a large part of the search for the etiology of the diseases and the nature of the complications must be under-The pathology of communicable diseases has not been studied as thoroughly as it should I am using the term pathology in its broad sense. It is known only partially by the majority of pathologists. It is closely related to the pathology of pediatrics. Hence the pathologist of a communicable disease hospital preferably should be well versed in the pathology of communicable disease and pediatrics, at least the latter. Otherwise his work will lose much value, will be very ordinary and will promise little for advance in the comprehension of these diseases until he attains such knowledge. This conclusion is an indirect outgrowth of studies of these statistics.

An outgrowth from a practical knowledge of such pathology has been the development of a better technic in the handling of diphtheritic croup. The value of the O'Dwyer tube has become considerably restricted. Only a few years

1927	112 (12) 72 (19)	5 43	16 6	(42) 289	18 2	14 5
1928	(19) 68	3 6	27 9	(64) 330	17 5	19 4

Note: Figures in parentheses in first column are deaths among intubated.

In 1928 measles was very widely spread through the city there being 53,629 cases in the entire city as against 39,750 in 1926, the previous epidemic year, and 2,101 in 1927 the intervening low year. 105 out of 210, that is 50%, of the cross infections in 1928 were due to measles. All secondary infections and especially those acquired after admission are important as causes of greater expense and possible death. The figures just given show the importance of our developing if possible some more adequate method of control-

ago there was a fair sized group of "chronic tube" cases living in the hospital. These children were without home life. Their care and schooling were financed by the city. All have been restored to their homes. Also tracheotomies were frequent. This has changed greatly. Intubation is seldom done Tracheotomies are very rare. Suction now is applied by a Sorensen pump through a soft rubber catheter passed through the glottis with the aid of a direct vision laryngoscope. This table indicates the progress we have made.

One mevitably questions whether adequate medical and nursing care is being given to each patient. We have been conducting time studies of the amount of nursing care required for patients of certain types. The time required varies a great deal as is to be expected. Our figures are only for absolutely necessary care. They are probably under estimations of what the patient should receive. This table shows the computations made to date. All of the figures are averages.

The Mixed or Observation Service is so variable in the kinds of diseases and the numbers of them present, the need for complete individual isolation is so great, and the physical features of the pavilions used for them necessitates so great an expenditure of time, that the cost in nursing hours is very high

I have shown you a few of the many ways in which we have employed our monthly statistics to teach us wherein we were weak and whether the reas d methods we substituted were effective.

TABLE VIII

 $\frac{13493}{9} = 1687$  Nursing Days

Employing these figures we have calculated the nursing requirements for the years 1927 and 1928, and for the three diseases, diphtheria, mensles and scarlet fever, the findings are as in Table IX

and to what degree I have tried to show some instances where we proved ourselves wrong and had to revise our ways. The great thing is to use such figures to discover the truth not to warp them in order to booster up preconceived notions.

## CONGENITAL BLADDER OUTLET OBSTRUCTION IN INFANCY AND CHILDHOOD\*

By MEREDITH F. CAMPBELL, M.D., NEW YORK, N. Y.

From the Departments of Urology, Pathology and Pediatrics of Bellevue Hospital and the Pediatric Service of New York Nursery and Childs Hospital.

LTHOUGH congenital obstructions at the bladder outlet are found at autopsy once in approximately 400 males, it is surprisingly seldom that the lesion is recognized and properly treated during life. It is interesting to note that while the condition was first described as an autopsy finding 127 years ago<sup>1</sup>, only in recent years has urological advancement enabled us properly to diagnose and treat these diseases. Young, in 1912, was the first to treat a case surgically.

The types of congenital bladder outlet obstructions which we will here consider are (1) contracted bladder neck, (2) congenital valves of the posterior urethra and (3) hypertrophy of the verumontanum. Congenital stricture of the deep urethra and congenital sphincteric spasm of neuromuscular vesical disease are so rarely encountered that consideration of these conditions may be wisely omitted from this discussion. symptoms of all of these various lesions as well as the pathological anatomy of the urinary tract above the site of the obstruction are identical; only the structural character of the obstructions differs. The basis of this report is a study of congenital obstructive disease of the vesical outlet as observed either clinically or at autopsy in 18 cases (oldest 14, most under 8). Of particular interest are the extensive destructive changes of the upper urinary tract; of prime clinical importance is the resultant nephropathy.

The congenital contracted bladder neck is characterized by marked submucus sclerotic atresia of the vesical outlet. The etiology of this anomaly is unknown. Histologically, tissue taken from these lesions shows submucus sclerotic infiltration with or without evidence of inflammation. In some instances the entire sphincteric ring is involved; in others but the lower segment of the orifice is pathologic. This latter picture is quite similar to the frequently observed median bar obstruction of adult males. In any event, the congenitally small vesical outlet does not permit free urinary drainage so that upper tract damage results. In six of our cases, the obstruction was proven to be of this type; in an additional instance, this diagnosis seems most likely. Of these seven cases, five were studied clinically, two were seen at autopsy.

Of particular interest is the case of a two-yearold male who cystoscopically showed a congenital contracted bladder outlet. Marked hypertrophic changes in the bladder wall were evident. There was present a diverticulum of the bladder dome

twice the size of the bladder proper and in this diverticulum was a stone two by three centimeters in size. The phenolsulphonphthalein excretion was 12 percent in two hours. Consent for operation was refused by the parents. The patient died in uremia four months later. In another case of this type of obstruction studied clinically, a three-year-old boy, four vescial diverticula were present together with marked upper tract infection, dilatation and damage.

Congenital posterior urethral valves are the most frequently observed congenital obstructions of the vesical outlet. In spite of their not infrequent incidence, to date but 62 cases have been reported. Only 27 of these have been operated upon. In most of the remaining cases the lesions were observed at autopsy. In our series, six were observed clinically and studied cystoscopically, four were autopsy cases and but one was operated upon.

These valves are mucosal folds within the posterior urethra and may either partially or completely block the urinary outflow. They usually extend from some portion of the verumontanum to the lateral urethral wall or, as in four of our cases, may extend posteriorly in to the vesical outlet itself. Occasionally these valves are unilateral as we have twice observed. In some instances the valves have no anatomic relationship to the verumontanum but may be located either in front of or posterior to the veru and assume the form of a diaphragm. The aperture may be large or small. In one of our cases, the mucosal valve formed a partial diaphragm across the lower portion of the urethra just in front of the verumon-In another instance, the valve was superimposed on the bladder outlet in the form of a crescentic fold and caused almost complete blockage with extensive upper urinary tract dam-A similar observation was recorded by Eigenbrodt in 1891.

These valves have been classified into three types depending on whether the folds extend anteriorly (Type I) or posteriorly from the veru (Type II) or whether they were entirely unassociated with the veru. (Type III) Of special interest to us was the finding of a Type I obstruction in a male who died at birth. Marked upper urinary tract obstruction had occurred in utero. Bednar<sup>3</sup> in 1840 reported an apparently identical finding in a still birth.

The etiology of urethral valves is unknown. Several theories have been advanced, the oldest being that of Tolmatschew (1870) who believed these structures to represent a hypertrophy of the normal urethral ridges or folds. The theory that

<sup>\*</sup> Read at the annual meeting of the Medical Society of the State of New York, at Utica, N. Y., June 6, 1929.

these valves represent a persistence of the urogenital membrane was advanced by Baz\*. On the basis of observations made while studying the embryology of the verumontanum, Watson\* deduced that the valves resulted from a fusion of the veru and overlying urethral roof. In one specimen he found three fibrous bands passing from the veru to the urethra above it. However, all of these theories lack proof and at present the origin of these structures is unknown. In certain cases (the iris diaphragm type) the valves obviously have no anatomical relationship to the verumontanum.

Hypertrophy of the verumontanum sufficient to cause urinary obstruction occurs rarely. Bugbee and Wallstein<sup>7</sup> reported the observation of seven cases at autopsy. At Bellevue Hospital, the lesion was encountered at autopsy but twice in 1204 male children. In one of these, although the enormously hypertrophied organ well filled the entire posterior urethra, it had not caused sufficient urinary obstruction to bring about any marked changes in the upper tract. Not infrequently in young boys we have observed marked enlargement, engorgement and chronic inflammation of the veru as the result of masturbation, but in these cases cystoscopy revealed no evidence of urinary back pressure.

Congenital urethral stricture and neuromuscular vesical disease have been dismissed with their mention.

In one case coming to autopsy but not included in this series, obstruction within the posterior urethra was found to be caused by a "Z" shaped urethral malformation just in front of the veru. As a result of the sharp kinking of the urethra upon itself, marked obstruction was present and was reflected in the destructive anatomic alterations of the upper urinary tract. I have not found a similar urethral anomaly reported elsewhere. Again, in a five-year-old boy complaining of frequency, cystoscopy revealed a marked enlargement of the median prostatic lobe identical in all respects with the picture of this lesion as observed in adult males. This lobe seemed nearly to occlude the vesical orifice; the very appeared nor-Oddly enough the vesical walls showed little evidence suggesting persistent back pressure. Removal of the growth was refused.

### UROPATHOLOGY

The destructive changes taking place in the urinary tract above the point of obstruction are identical, irrespective of the anatomic character of the blockage. Urinary stasis is the first ill-effect produced. This is at once followed by dilatation and hypertrophy of the urinary musculature. Trabeculation may become extreme; diverticula frequently form as in six of our cases. With the advent of infection, inflanmatory selerotic atony of the bladder and ureteral walls becomes the

end result. Not infrequently the dilated atonic ureters become as large as the colon, tortuous, sagging and often kinked upon themselves. Because of the marked increase in size of the treters, on abdominal palpation they may be thought to be intestines.

As a direct result of the accompanying ureteritis, the function of the uretero-vesical sphineters is impaired of lost. Bladder urme easily regurgitates to the renal pelvis. This condition is readily demonstrated by cystography

The gross changes caused by the greatly increased intraurinary pressure are reflected in the kidney by dilatation of its pelvis with compression and thinning out of the renal parenchyma Infection speeds up this process. The end result is both architectural and functional destruction of the organ; not infrequently the parenchyma is reduced to a thin shell. When the renal damage is extreme, the patient usually dies of uremia. Unfortunately, in the majority of these cases, the true nature of the condition is not recognized until autopsy.

### Symptoms

The symptoms of vesical outlet obstruction may be divided into those of urinary difficulty and those resulting from renal damage and urinary infection. Of the first type, urinary frequency together with great difficulty in voiding is constantly observed. From the history it will be learned that these symptoms have been present since birth, that urination is accompanied by great straining, that there is always great difficulty in starting the stream and at the end of urination, dribbling may occur. Paradoxical incontinence may lead to the erroneous diagnosis of enuresis but persistent lower abdominal pain or the presence of a protuberant chronically distended bladder should at once suggest vesical retention. As in one of our cases, there may be recurring attacks of acute retention requiring catheterization. In another case reflection of the vesical distension to the loins (kidneys) was observed. This loin pain coupled with the marked pyuria and intermittent fever (a triad often observed in these cases) usually prompts the diagnosis of chronic pyelitis. When dysuria is marked, the diagnosis of acute cystitis usually satisfies the physician.

The systemic symptoms appear as renal damage becomes pronounced. They are predominantly manifestations of uremia and may be evidenced by both gastro-intestinal and central nervous system upsets. Indigestion, malaise, nausea, vomiting and loss of or failure to gain weight may misdirect the attention to the gastro-intestinal tract. Hyperirritability and headache may be the first neurologic symptoms. Later the patient becomes drowsy and, as the disease becomes extreme, lapses into coma. Because of the lowered general resistance, intercurrent infections are often ter-

minal; pneumonia or acute renal infections are usually fatal complications.

Fever, of low grade as a rule, quite regularly accompanies the urinary infection. In the event of an acute infectious exacerbation, fever with chills and other evidence of urinary sepsis will be noted.

## DIAGNOSIS

To one experienced in this field of medicine, the recognition and diagnosis of these various congenital bladder outlet obstructions is comparatively easy. The frequency and dysuria at once direct attention to the urinary tract. Pyuria evidences urinary infection. The palpation of a distended bladder obviously localizes the obstruction to the lower urinary tract. In many of these patients, the greatly distended ureters and kidneys may be palpated. Before subjecting these young patients to a cystoscopic examination, valuable pre-cystoscopic data should be obtained and in many instances the probable diagnosis will be indicated by this data.

A complete urinalysis including culture is imperative. The two-hour phenolsulphonphthalein estimation should be made and the urea nitrogen or non-protein-nitrogen content of the blood plasma determined. A plain roentgenogram of the genito-urinary tract will indicate the presence of complicating calculus disease (other than uric acid which usually does not show in films) or congenital spinal defects, notably spina bifida. Because neuro-muscular vesical disturbances are so commonly associated with spina bifida and may so closely simulate congenital vesical outlet obstruction clinically it is of utmost importance to rule out the possibility of a neurogenic element in the vesical retention.

Because a large bladder residual is usually present, the rapid emptying of this viscus for the determination of the residuum is, as a rule, unwise. However, the presence of a residuum is assumed in these cases and will be found to vary from a few cubic centimeters to 600 cc. or more. The advisability and technique of gradual decompression will be considered under treatment. Not until the bladder has been decompressed and all evidence of renal shock has disappeared should one consider cystography or cystoscopy.

Having acquired this pre-instrumental laboratory and roentgenographic data, a cystogram is made. The bladder is emptied of urine and refilled with 5% sodium iodid to a point at which slight vesical distension is noted. Stereoscopic roentgen exposures are made and the resulting films will indicate the regularity and form of the bladder outline as well as the integrity of the ure-teral sphincters. Diverticula and large sacculations are easily made out; in many cases iodid reflux up the ureters outlines not only these channels but the renal pelves as well.

When the obstruction is in the posterior urethra near the verumontanum, a funnel shaped vesical outlet is not infrequently seen in cystograms and requires differentiation from that which so often accompanies neuro-muscular vesical disease. The cystogram of contracted bladder neck is indistinguishable from that of spastic neurovesical disease. The differential diagnosis between posterior urethral valves, contracted vesical outlet and neuromuscular vesical disease must be made by cystoscopy.

While we quite regularly perform complete urological examinations including pyelography in five-year-old girls without general anesthesia, it is rare that one can cystoscope a male of less than eight years without complete anesthetization. Over this age, certain patients will co-operate well in the examination if novocain is first used locally in the urethra. In all cases a preliminary hypodermic of morphine serves to quiet the patient and allay in part the extreme apprehension which these young children so regularly manifest.

We have found that the passage of a 15F. sound will greatly facilitate the subsequent passage of the infant cystoscope. It is well to note here that in many of these cases urethral instrumentation is extremely difficult. Urethral catheters, sounds and cystoscopes are often stopped by the urethral obstruction so that only a filiform bougie or a fine ureteral catheter may be passed to the bladder. Great difficulty may be encountered in the passage of even these latter instruments since they not infrequently engage in the folds or pocketings at the site of the blockage and unless one is successful in penetrating the aperture of the obstruction, the instrument cannot be made to enter the bladder without urethral injury. It is equally difficult to penetrate the aperture of the obstruction retrograde through a cystotomy wound because of these pocketings. When urethral valves are present, they always balloon toward the meatus and may then form deep pouches in which instruments will be caught. When it is found impossible to pass a cystoscope, the obstruction may usually be observed through an endoscopic tube.

Unquestionably the best instrument obtainable today for the examination of the posterior urethra in the young is the new infant cystoscope of McCarthy. It permits close observation of this channel. Young warmly endorses small endoscopic tubes for the inspection of urethral valves. The cystoscopic features of these obstructive lesions need not be described here; they are well known to most competent urologists.

Cystoscopic study reveals the character of the obstruction as well as the secondary back pressure changes of the bladder wall. Hypertrophy and elevation of the trigone and trabeculation with or without diverticulum formation are com-

monly observed. The ureteral orifices may gape and in one instance we were able to introduce the cystoscope well into the ureter Young and McKay8 reported a similar observation in which the renal pelvis was thus explored While ureteral catheterization will reveal the separate kidney function, this procedure is unnecessary for the establishment of the correct diagnosis

### TREATMENT

Having determined the nature of the obstruction, its removal constitutes the treatment these young patients we must institute the same pre instrumental and pre-operative preparation and treatment as that employed when prostatectomy is anticipated in adult males. If a large residual is present or if the patient is in chronic complete retention, gradual decompression of the bladder should be carried out Failure to observe this indication may result not only in an immediate post operative but even in a post-catheterization uremic death. Gradual emptying of the bladder can usually be satisfactorily carried out by inserting an indwelling ureteral catheter to the bladder In some instances, the slow emptying by this method will require two to three days. Once the bladder is thus emptied, continuous vesical drainage should be carried out until the general physical condition of the patient as well as the renal function tests, blood chemistry, etc are established at a constant level We have under observation at the present time, a three-year old male with a contracted bladder neck who, when we first saw him, was clinically uremic Only a trace of phenol sulphonphthalein was executed in two hours For the past six months he has been draining suprapubically and during this time remarkable improvement has occurred. He is now ready for the removal of his obstruction

Free bladder dramage either by an indwelling urethral catheter or by suprapubic cystotomy drainage together with an enormous fluid intake constitutes the best pre-operative treatment these indications and methods are observed, the likelihood of surgical success is greatly enhanced Drugs are of little value in this pre-surgical preparation, water in abundance is the best medicine.

When the patient is thus properly prepared and ready for operation, contracted bladder neck obstructions may be punched out trans-urethrally or may be removed through a suprapulic approach. The removal of a generous segment of the obstruction is the therapeutic indication While the bladder is open, calculi may be removed or as in one of our cases, diverticula may be resected

Urethral valves have been destroyed by fulguration (9, 10) punching out, perineal section, suprapubic destruction or by rupturing with a steel sound passed into the urethra11 of our cases, this latter method proved efficacious By trans-urethral fulguration or by suprapubic retrograde approach, destruction of a hypertrophied verumontaniim may be accomplished These various therapeutic procedures are highly technical and should be attempted only by those skilled in such procedures and anatomically oriented in the posterior urethra and vesical out-

Pollowing operation, a forced fluid intake by mouth, protoclysis or hypodermoclysis together with general supportive measures must be instituted As a rule, these young patients recover rapidly from these urologic procedures and, if the obstruction is sufficiently destroyed, are able to void normally In cases presenting marked renal damage, one may wisely err on the side of doing too little at one operation, Young even advises punching out but one valve at a time when there is any question as to the functional integrity of the kidneys

#### SUMMARY

Congenital vesical outlet obstruction occurs once in approximately 400 males. The clinical manifestations are strikingly similar to those of prostatic obstruction in adult males use of modern urologic methods and instruments, the diagnosis of these conditions is comparatively easy to make and treatment is easy to carry out Therapeutic measures are directed toward the restoration of renal function The removal of the obstruction is but a step in the surgical treat-The prognosis depends on the degree of renal damage and also is in direct ratio to the knowledge with which the urologic indications are observed and the skill with which they are carried out

# EDUCATION, HEALTH, AND HEALTH EDUCATION\* By FRANK VAN DER BOGERT, M.D., SCHENECTADY, N. Y.

DO not believe that any one will question the statement that too much culture is dangerous. The physical makeup of the human race has been influenced by it for centuries and influenced badly. Sterility, the difficulties of childbirth and adolescence, nursing failures, all were practically unknown to the uncultured savage. Studies of the noble families of Europe have shown that most of them die out within 100 to 150 years, generally not living beyond the third generation. The families of great scholars, artists and statesmen have shown a similar tendency and the offspring of men of science have apparently decreased more than half in a single generation. All this is not due to birth control, the change from a free life to a restrained one favors sterility in both animals and man. The sterility of the upper classes of society is in part at least comparable to that of animals in captivity in that it depends upon unnatural conditions of living.

There can be little doubt that childbirth is slowly becoming more difficult. Its dangers to the mother have been lessened to a great extent by improved obstetrical technique but pediatricians realize the greater danger to the child. Dillenbaugh was impressed by the infrequency of deformities and malformations among the Indians and Catlin by the astonishing case and success with which the Indian women passed through the ordeal of delivery and vouches for the oft-repeated story of the Squaw who tied her horse under the shade of a tree and, before night, overtook her travelling companions with her infant in her arms.

Then too, the uncultured savage has little difficulty in nourishing her offspring for a period of years. We must not content ourselves with the assurance that all that is required for the production of a race of nurslings is encouragement. The problem is a much deeper one and depends for its solution upon a reversion to a more natural manner of living and upon the conservation of animal instincts. Towner believes that it is to be solved first by givng intellectual women a different education from that of men and goes so far as to say that so long as their educational limits can keep these women within the mental range of children some of them may still be happy mothers.

The greatest lesson learned by Margaret Mead

from her study, for the American Museum of Natural History, of the simple civilization of Samoa was that adolescence is not necessarily a time of stress and strain but that cultural conditions make it so.

Franklin, writing to Richard Jackson in 1753, tells of "the little value Indians set on what we prize so highly under the name of learning." At a treaty between some colonies and the Six Nations, when everything had been satisfactorily settled, the British Commissioners told the Indians that they had in their country a college for the instruction of youth, where they were taught various languages, arts and sciences, that there was a particular foundation to defray the expenses of the education of their sons and that, if the Indians would accept their offer, the English would take half a dozen of their brightest lads and bring them up in the best manner. After consultation, the Indians replied that some of their youths had been educated at that college but that it had been observed that for some time after they were absolutely good for nothing, being neither acquainted with the true method of killing deer, catching beavers nor surprising the enemy.

Unfortunately for the relief of our difficulties, education is only one factor in the production of what we call civilization. It must, however, be conceded to be the determining factor in childhood since the whole life of the child must revolve around the school.

Medical and surgical progress, including medical supervision of school children, has done much to alleviate and neutralize the effect of unnatural living but on the other hand they have apparently encouraged an attitude toward life regardless of rational living and expectant of relief when injury occurs. The adult lives as it pleases him to live and looks to medicine and surgery for repair. It is reasonable to believe that when he recovers, and he usually does, he is not quite as good as before, no other machine is. This attitude is reflected in the bringing up of our children and we force them beyond the limit of tolerance. call them undernourished, feed them milk and send them to the clinics for removal of areas of focal infection. The nutrition problem is a broader one and depends for its solution upon a preventive medicine which actually prevents rather than repairs, which develops a resistance through contact with natural rather than with artificial stimulants.

Even if we were selfish enough to advocate living in the present and letting the future take care of itself there is real doubt that we are fitting the individual for his part in the world. Re-

<sup>\*</sup> Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y., June 6, 1929.

cent researches in the field of learning have shown pretty conclusively that better results have been obtained when accuracy rather than speed was emphasized As Di Meyers says in his article on the mental hazards of the schoolroom the reason why our children work so slowly is because we try to make them work so fast 'Then why," he asks, "all this human torture only to produce inferior learning products?"

The life of the school child in America today is as strenuous as that of the business or profes sional man or woman and the standard is the same "efficiency." He must rise early, hurry his breakfast and, often without time for evacuation of the bowels, rush off to school. If he is not there on time he is penalized. He is given more or less credit for regular and perfect attendance which influences him, or his parents for him, to disregard slight indispositions, ordinarilly treated by rest, or the prodromal symptoms of contagious disease so dangerous to those with whom he comes in contact and so rarely detected by a medical school inspection until too late.

After a morning of organized study, more or less competitive, with possibly a short period of organized play, he is sent home to bolt his lunch because he must be back at his desk at the allotted time often too short to allow of a quiet restful meal which is so essential to normal digestion. He must do this or he must be content with a pienic affair planned for easy transportation rather than ease of digestion and assimulation. The other alternative is the lunch room or tuck shop with its temptations to pulatability rather than nutriment.

If animal instincts occasionally get the better of him or if he fails to complete his allotted task in the time allowed he is kept after school and deprived of the little fresh air and sunlight usually allowed him at the close of the day and in the higher grade he is given sufficient home work to interfere with his sleep. Has any fired business man more to complain of and is it not altogether likely that the speed at which we adults are living, admittedly too fast, was developed in childhood and has gotten beyond control. Difficult as it is tor the man to do so, he can, if he will, break away, but the child if he escapes is thrown linck into the stream, thrown back by the law often in spite of the protests of his parents, and vet Darwin found that he could only safely concentrate for two hours a day

It is astounding to learn what his happened to the curriculum within the past few years. Things formally taught in college are now taught in the high school and what used to be taught only in the high school has descended to the lower grades. Increase of speed, more efficiency, less actual knowledge because of absolute imbility to master even a small percentage of it all. It does look, as Buchholz contends, as if we were spending more money for less education and that the whole situation has become a competition between communities for the aggrandizement of the one who educates at the expense of the educated, another evidence of American extravagance

But what can we do about it? I think we can do a great deal. The man who teaches children will listen to the man who studies them. My feeling is that the mental hazards will to a great extent take care of themselves if the physical are climinated. Shorter school hours allowing for more time at meals and an after lunch rest period with a little more time in the morning and evening for natural living indoors and out will certainly insure a clearer brain and lessen the mental strain

Nothing is more important to the growing child than properly prepared and quietly consumed meals at regular hours. No other nutritional program is rational and no other nutritional program need be considered if study hours are properly arranged. There seems to be no tenable argument for the midmorning lunch community feels that it must nourish its under fed let arrangements be unde to deliver the nourishment at the home or serve a breakfast at the school at community expense. It has been amply demonstrated that food consumed at other periods interferes with normal appetite and digestion Under the present method of requiring payment, as one of my colleagues has expressed it, it is the child who does not need the milk that has the fifteen cents Judging from local conditions school milk is becoming less popular. In Sche nectady with a student population of between nineteen and twenty thousand the number of pupils taking milk has decreased from 3500 to 1200 and it is exceedingly interesting to learn that in four of the schools, all in the less prosperous neighborhoods where it is presumably needed most, only 83 of the 1200 pupils are recerving it

The greater value of rest at midday before exhaustion has occurred has been demonstrated by unimal experimentation

And now comes an effort to lower the age limit of school attendence to two years by the inclusion, in the public school system, of the nursery school The prospect of immediate action does not seem good because of its cost even though the resources of the taxpayers seem unlimited where education is concerned and Dr Patty Smith Hall, its chief advocate, says we are not fully civilized today Besides it may be difficult to secure a sufficient number of teachers of the type that Dr Hall de According to her requirements the nursery school teacher must have some of the knowledge and skill of the trained nurse together with the attitude and ability of a wise, intelligent She must have a goodly share of the medical knowledge which pediatricians are sup posed to possess. She must be well inducted into

practice of others than we used to see in my interne days.

There may be some men still doing the bloodclot operation but if so they are unknown to me-

The Chronic Running Ear: The chronic middle ear abscess appears to be on the wane and there are relatively few radicals done at the hospital I attend.

In the non-operative treatment of the chronic running ear everything has been tried from bichloride of mercury, through all the rainbow of the aniline dyes, argyrol, dry treatment, wet treatment, ether, S.T. 37, vaccines—their name is legion.

Ionization of zinc by the galvanic current is now being advocated but it too may join the "rubber band around the neck" treatment of my

interne days.

We hear but little of ossiculectomy and the modified radical or Heath operation does not have many adherents.

The use of blood transfusions in lateral sinus thrombosis has come within these twenty five years and Tobey of Boston has added the manometer test as a means of detecting a plugged sinus.

The Labyrinth: There are few of us—outside the large cities—who dare attack the labyrinth and it is well that this is so. There probably has been no improvement on the labyrinthine operation of John D. Richards. But the physiology and pathology of the labyrinth has been given a great deal of high-powered thought. The whirling and caloric tests of labyrinthine function, as worked out by Barany, Isaac Jones, Fisher Eagleton and others have made out of the otologist something more than a repair man. He can become, if he wishes to give up the time to it, a diagnostician, a neuro-otologist.

The recent visit to this country, of Brunner, inspired a fresh impetus in the pupils of the numerous classes he lectured to. It is an interesting and baffling study. To myself, and to others to whom I have talked, the subject seems so easy when one listens to a good teacher—and Brunner is that—and so difficult when one comes to apply the knowledge to his patient in the privacy of his own office. I confess that the best I can do is to say that the patient has, or has not, a dead labyrinth or a relatively slow labyrinth and let it go

Labyrinthine tests have a big disadvantage. They are upsetting. Ask any office girl who has cleaned up after a too vigorous test. And as Brunner said of the malaria treatment in cerebrospinal syphilis "when a patient comes to you well, and goes with sickness away, it is not so good."

Sonnenschein, McKenzie and Fowler have written reams in attempting to teach us how to make standardized hearing tests. Prior to the invention of the Audiometer the estimation of hearing was far behind that of vision in both accuracy and consistency. The human voice

varies, the acoustic properties of our offices vary, the outside noises vary, even tuning forks vary. Prior to the Audiometer, possibly the Ingersoll watch was the most constant standard. It at least was cheap and universal. Now with the Audiometer the otologist in San Francisco, Memphis, Montreal and Utica can record a patient's hearing in a way that means something to any other practitioner. He can go into court and give his testimony on the loss of hearing in percentage terms, as courts, the lawyers, the family doctor and the people in general like to have it.

In 1929, as in 1900 and every year between, it is a safe bet that at least once a year some otological author after nine months or more of gestation will give birth to a paper on tinnitus that will be long and learned, exhaustive and exhausting, and the last word on our knowledge of this baffling affliction. It is a startling example of the triumph of faith over experience that we privates in the ranks will read such articles diligently and if anything new is suggested will try it hopefully on the next patient with the same disappointing results.

We began with local treatment of the Eustachian tube and middle car. We went on from there to amputating turbinates and resecting septums. These failing we tried bromides and hydrobromic acid. Then came pilocarpine internally. Now comes the removal of the tonsils, teeth and other foci of infection, cocanization of the sphenopalatine ganglion, severing the eighth nerve, destruction of the cochlea, thyroid extract, and adrenalin, digitalis and strychnine if the systolic pressure is too low, ligation of the common carotid artery and the bombardment of the hearing apparatus by the various noise makers.

Nerve deafness and otosclerosis still remain an unsolved problem. We know more about their etiology but just as little about their satisfactory treatment as we did in 1900. Otosclerosis has had a great deal of high-powered study devoted to it. Through the researches of Gray and others we know more about it, but as little about what to do for it as we did in the early years of the century. One more disease or subdivision of the causes for deafness has been worked out by Jennings of England—the deafness of osteitis deformans of Paget's disease.

A step in the right direction is the program of research work by the committee of the American Otological Society under J. Norval Pierce for the study of otosclerosis. This committee will work with funds supplied by the Otological Society and the Rockefeller Institute.

The Throat: Now for the throat. In New York in 1906, the indication for the removal of the tonsils was their hypertrophy. In Rochester in 1929, as elsewhere in the United States, the chief indication for the removal of the tonsils is their visibility. Indeed, as one essayist has said, "If I send a patient to a specialist with a

question as to the presence of infection in the patient's tonsils and that patient returns to me with his tonsils still in his head, it is because that specialist was out when my patient called " With quantity production in tonsillectomies has come many improvements in technique and while dissection and snare remains the method of the art-1st, the Sluder method and its modifications have enabled the general practitioner as well as the specialist to remove tonsils with neatness and despatch. The result is that we do not see the mangled pillars and the amputated uvulas that we used to see when snare and dissection was the implement of the tyro as well as the experienced. This generation owes a great deal to the late Dr Sluder

In 1906 we were doing tonsils with the Mac-Kenzie Mathieu tonsillotome although in our hospital Mosely, Carter and Hurd, particularly, were teaching and practising the use of dissection and source. In those days, the removal of the tonsils for 'ocal infection was in its infancy and the tonsils taken out were largely the hypertrophied tonsils and adenoids of childhood, so that the MacKenzie or Mathieu instrument worked fairly well, and if in many cases the gland was amputated instead of extirpated, why the object of the operation had been attained anyway,-the clearing of the air passages. Adenoids were done with curettes and the Brandigee forceps, an instrument that occasionally nipped off a bit of the posterior edges of the septum. We did a large number of tonsils weekly even in those days although few of us realized the tremendous possibilities of the field

Now in Rochester, if we didn't discover the tonsil, we fell at least that we have done considerable work in its development, and the study of Kaiser on 5000 tonsillectomies has become a classic. But while Kaiser studied his cases chiefly with a view to preventing the diseases of childhood, internists from 1907 on, have urged the removal of the infected tonsil for hypertension and hypotension, for nephritis and bronchial asthma, for choroea and arthritis, for the blood dyscrasias, and hyperthyroidism, for malnutrition and such local manifestations of systemic disease as intis corneal ulcers and ezzemas.

It is a relatively easy operation to do, and whether the tonsil has or has not a function, its removal seems to be fraught with little or no difference to the body's economy. It is therefore unfortunate that the eradication of these glands not infrequently fails to correct the systemic disease for which relief was sought. The transformation of the tonsil into fibrous tissue by a-ray and Radium seems to be quietly passing into the sargasso sea of dereliets. It promised much—no danger, no absence from work, no hemorrhage—but in after months of treatment it, in many cases, left behind considerable infected tonsillar tissue and in a few cases damaged the parotid

gland so that the patient had a dry mouth. The latest method of dealing with the tonsil—surgical diathermy—is still in the experimental stage it promises all that the 1-ray method hoped to get, but a recent criticism of it in the J. I. M. A states that many cases thus operated on show stumps of infected tonsils left behind, and anyone who has had experience with the amputated tonsil and the cauterized tonsil knows the possibility of quinnsy and blocked drainage from such fragments of infected tonsil.

If there was such a disease as Vincent's Angina in our clinics in 1906-1908, I fail to recall it. In 1913 the N-Y-STATE JOURNAL had a paper by Cocks, in which he describes the difficulty of curring it and gives a host of remedies which have been tried. A later paper states that Salvarsan has been used in one or two cases with success and later still comes the idea that with cither Salvarsan or Sodium Perborate we have a rehable remedy. After the soldiers came back from France, "trench mouth" became a comparatively common disease in this country.

The biggest advance in lary ngology since 1906, has been due to Chevalier Jackson. Halstead in a paper before this society in 1908 tracing the development of bronchoscopy and esophagoscopy, says "Chevalier Jackson took the Einhorn tube and made out of it a gastroscope."

In 1906 we were still extracting foreign bodies from the laryin by the MacKenzie forceps. If they went further than that—although I can only recall two peanut cases that did—a tracheotomy was done, and these two cases at least promptly died. In 1907 Jackson published his book 'Tracheo-bronchoscopy, Oesophagoscopy, and Bronchoscopy," In 1918, this great master came to our hospital and demonstrated the direct method of removing foreign bodies from the bronch. Although I got a good start, being personally instructed by Dr. Jackson on how to hold the head, I failed to continue with the specialty possibly because I found the office of headholder a very irksome position.

Since those days improvement in technique has come so thick and fast that bronchoscopy has developed into a specialty almost over night. It has a Society and a Journal of its own and an armamentarium that requires the American in ventive trait for its genesis and a Ford truck for its transport. Its use has extended to bronchial and lung affections, and the varied instruments for removing every conceivable kind of foreign body are a far cry from the umbrella probang the coin catcher, the MacKenzie forceps and the hunt and push method that preceded Chevaher Jackson.

Colds continue to be the cause of the greatest economic loss in America. There has been no improvement in the morbidity since the days of our grandfathers. In spite of the removal of the tonsils and adenoids, vaccines, feeding of vita-

mins, the saccharine products of the hirsute Smith Brothers, the cold and cough continue to he the chief menace to the health of our children and the chief cause of the sinusitis and mastoiditis of their elders. During the war an army surgeon noted the freedom from colds of the workers in chlorine factories. The result was that between 1920 and 1924, all conventions of pharyngologists showed a large proportion of booths exhibiting apparatus for liberating chlorine fumes. The day of the cold and its complications was to be gone forever. No more rhinitis, sinusitis or mastoiditis. But there is a divinity that looks after our specialty and if you glance through the pages of the medical journals of the current month, you will search in vain for the chlorine manufacturing machine. It has gone to join the dodo and the electric battery. In its place has come the sunlamp.

Vaccines and Serums. When I was an interne, the announcement of the discovery of Sir Allmeroth Wright and his associates regarding opsonins and the opsonic index of the blood caused considerable comment and it was felt by some of us that this would be the method of treatment of the future. Later on came the work of Hiss and Dwyer with leucocytic extract, and papers read before this society by two of its most esteemed members extol the virtues of this preparation in some of the brain and blood complications of the middle ear abscesses. In the whole field of vaccines, serums, foreign protein therapy, antigens, immunogens, phlyacogens, erysipelas serums, excepting only diphtheria antitoxins, there has been little of cheer and much of disappointment so far as they covered the treatment of diseases within our specialty. For one man who obtains success with vaccines for colds, furuncles, sinusitis, suppurating ears, there are twenty who are disappointed. My feeling is that vaccine therapy has done far more for the compilers of medical dictionaries and the pharmaceutical houses, than it has for the laryngologists and their patients.

Hay Fever and Asthma. A relation of hayfever and asthma to the nose has been known of course for years and so our specialty has had more than a passing interest in these difficult

problems.

When the reader settled in Rochester in 1909, John O. Roe, a master of plastic nasal surgery, was preaching the doctrine of the cure of asthma and hayfever by nasal surgery. Roe's nasal surgery was well in advance of his time, but we are not so enthusiastic over the reflex nasal irritation as a factor in hayfever or bronchial asthma. Since 1900 the treatment of hayfever and asthma has come more and more into the hands of a new species of specialist—the serologist—and with him has arisen a new doctrine and a new vocabulary.

The "Eye of newt and toe of frog Wool of bat and tongue of dog

Adder's fork and blind worm's sting Lizard's leg and owlet's wing and the other contents of the witches' cauld-

had nothing on the case box of the conscientious serologist with its extracts of wheat, milk, cat dandruff, chicken feathers, horse serum, staphylococci and what not, each and all of which he jabs into his victim's arm in an attempt to find out what he reacts to. However, rhinologists have been reluctant to let go of the asthmatic and the hayfeverite, and if we have to a large extent abandoned, not necessarily the doctrine of reflex nasal neurosis but the hope of getting anywhere by that route, we have now taken up the problem from a new angle, that of focal infection. So far the results are not any too encouraging, but let us hope that the next twenty-five years will see a better batting average. Tonsils have gone into the port of missing organs, we are now attacking the ethmoids.

Local Anaesthesia. Since 1906 we have improved our technique in local anaesthesia chiefly in the substitution of novocaine for cocaine in injections and in the use of nerve blocking wherever feasible instead of tissue flooding. The work of Ruskin and Sluder on the spheno-palatine ganglion has been of great practical value to our

specialty.

and not to practise both.

Prior to 1906 the old specialty of Eye, Ear, Nose and Throat was divided fairly well among the older men, at least into its two great divisions, the Eye and the Ear, Nose and Throat. In most cases the division was one that came after a number of years practise in the combined specialties. I notice however that with the younger men coming on there is a very definite trend to select either ophthalmology or oto-laryngology

There has been also a tendency to confine the practise of bronchoscopy to one or two individuals in a community. This is as it ought to be. There are not enough cases in a city even of 300,000 to keep more than one or two men expert and if all the cases are spread thinly around among all those doing oto-laryngology, then the patient suffers physically through the trauma produced by the inexperience of the surgeon and the surgeon suffers financially through the overhead of the highly specialized tools he must employ.

Our specialty has gone a stage further and produced specialties within a specialty such as the plastic nasal surgery of Sheehan and Carter and the laryngectomies of MacKenty.

Thus we see that with the passing years, the definition of a specialist as "one who knows more and more about less and less," becomes very apt.

The Accessory Nasal Sinuses. While there is nothing definitely new since 1906 in operative procedures on the accessory nasal sinuses, these cavities are attracting more attention.

Whether because the upper respiratory tract betteria are seeking a new habitat or because of better diagnostic facilities, the disease "sinusitis," has usurped the place once held by "appendicitis" and "my operation" as a topic for five o'clock teachitter

The antrum particularly is a very fertile field of investigation not only in the very evident infections of this space but as a possible hiding

place for foci in systemic diseases

The occasional iniraculous restoration of sight to the blind by a well done ethmoidectomy or sphenoidectomy has resulted in an enthusiasm for masal surgery for the relief of various eye pathol-

ogies among our radicals

Here again, the conservative wing has found it necessary to remind the enthusiasts that some of these cases cured by surgery would have got better by time or conservative measures and that a little more study in cases of retrobulbar neuritis that did not respond to nasal surgery would have shown them to be due to multiple sclerosis

The stereoscopic 1-ray picture, the improvement in trans-illumination and the use of lipoidol for diagnosis are probably the chief changes in technique during these twenty-three years

### Conclusions

The last quarter of the nineteenth century oto laryngologically speaking was characterized by sprays and inhalations, gargles and prints, medication locally and systemically. Its slogan was 'Let us spray." There was operative surgery of course but it was done to remedy a local condition

The years since then have been marked by bigger and better surgery not only to remedy local conditions, but as a panacea for almost

every ill that flesh is heir to

It is a question whether we have not been too optimistic in this respect. There are many of us who are disappointed in that so much excellent surgery should be so barren of results. Our specialty has been subjected to considerable criticism not only by writers of fiction, but by eminent men of our own calling.

You temember Dr Roscoe Geake the oto larvingologist in Lewis Sinclar's "Arrocusinth' Ile believed that tonsils had been placed in the human organism for the purpose of providing specialists with closed motors. A physician who left the tonsils in any patient, was, he felt, foully and ignorantly overlooking his future health and comfort. His earnest feeling regarding the masal septum was that it never hurt any patient to have part of it removed.

And Shambaugh of Chicago, who has spoken freely on this subject, says in a study of 290 cases of inner ear deafness—the unpleasant fact stares us in the face that of these children 123 had their tonsils removed for the purpose of improving an ear condition which could not be influenced in the slightest by any operation on

the nose or throat"

In spite of these criticisms. I think we have very good reason to be satisfied with the prog ress in oto laryngology There has been a big advance not in inventions comparable with radio or the aeroplane, but in the better doing of the old procedures and in the instruments of precision and diagnosis with which we work. The younger men are on the whole better prepared than we of 1906 or before. Their mastoids are neater their tonsils show cleaner fossie their submu cuses are straighter. They are surgically more at home in the accessory nasal sinuses. Where the older generation regarded the ethmoids and sphe noid with a respect that amounted to cowardice, the younger men rush in where we a little nearer the angels fear to tread

The oto laryngologist of the next twenty-five years will be, if the American Board of oto laryngology has its wiy, a specialist who has given considerably more thought and study to the physiology and purpose of the structures of the nose and throat than his predecessors, and

has no less dexterity in their removal

When that day arrives our specialty will be a more scientific if a less lucrative profession, and we specialist physicians will be more valuable to the community

## KERATITIS EXFOLIATIVA COMPLICATING DERMATITIS EXFOLIATIVA (ARSPHENAMINE)\*

By DANIEL B KIRBY, MD, FACS, NEW YORK, N Y

From the Department of Ophthalmology College of Physicians and Surgeons Columbia University

THERE are several reasons for bringing this subject forward. The first is to discuss the normal and pathological exfoliation of the cornerl and conjunctival epithelium. The second is to offer an analysis of the ocular lesions which

appear in derintitis exfohativa due to the arsphenamines, and to draw a logical malogy between the eye and skin lesions. The third is to emphasize the danger of ocular complications in the treatment of lues.

The subject might well have included Conjunctivitis Exfoliativa These terms are not found

<sup>\*</sup>Read at the Annual Meeting of the Med cal Society of the State of New York, at Utica N Y, June 6 1929

in the literature, but the lesions were so evidently exfoliative in nature and so like the process in the skin that the terms Keratitis and Conjunctivitis Exfoliativa were thought to be quite proper and descriptive of the lesions.

In the normal skin there is normal exfoliation of the most superficial layers of the epidermis. Replacement of cells is constantly going on from the basal cell layer. The shape of the cell undergoes a gradual transition in its progress from the basal to the cornified squamous layer. The nuclei become shrunken and stain less densely as the cells approach the surface and the cornified opaque surface cells may be regarded as having very little vitality, and no power of reproduction.

A similar condition exists in the corneal epithe-The most active cells are the basal and The more superficial cells are not cornified but there is evidence that they have less vitality than the deeper cells. The histological conditions are therefore such that we may judge that there is undoubtedly a normal process of exfoliation or desquamation of the most superficial cells of the epithelium of the cornea and conjunctiva as there is of the skin. There need not be left any gaps in the surface or any tendency to stain with fluorescein. In smears from the normal conjunctival sac, one usually finds squamous epithelial cells. The rate of normal exfoliation and regeneration is not known and could not accurately be worked out. Experiments would necessarily be based on abnormal conditions. The rate of regeneration of the epithelium after wounds is known to be very rapid, as large abrasions of the surface of the normal cornea have been observed to heal in 24 to 48 hours. The conjunctival epithelium heals less rapidly than the corneal.

Matsumato<sup>1</sup> found in tissue culture that the two inner layers of the corneal epithelium were concerned with regeneration, but Verrijp2 told me that in his experiments he had found all layers able to divide and multiply.

In a number of conditions, one may observe pathological exfoliation of the epithelium either of one or of several layers or of the entire thickness with exposure of Bowman's membrane. In all of the cases of keratitis and conjunctivitis in which there is epithelial loss without ulceration, there is pathological exfoliation of one or several layers of epithelium.

- 1. Cases without opacity but showing minute punctate stain with fluorescein.
- Various conjunctivitides.
   Traumatic and chemical erosions of the conjunctiva.
  - 4. Keratitis epithelialis punctata (Koeppe).
- 5. Any cases showing edema of the cornea as produced by cocaine, glaucoma, iriod-cyclitis, endophthalmitis, etc.
  - 6. Keratitis e lagophthalmo.

- 7. Keratitis herpetiformis.
- 8. Keratitis neuro-paralytica and Dystrophy.
- 9. Complicating keratitis profunda, sclerosing and interstitial.
  - 10. Dendritic and filamentory keratitis.
- 11. Complicating certain exanthemata and dermatitides.
  - 12. Traumatic and recurrent keratitis.

Parsons<sup>3</sup> in commenting on edema of the cornea says: "The liquid effused in and between the cells diminishes their coherence, so that the superficial cells fall off. This desquamation is never entirely absent in cases of acute corneal disease, its intensity depending on the degree and on the special character of the inflammation, being found par excellence in neuro-paralytic keratitis. In the slightest degrees single cells only are exfoliated; in severer cases whole layers of cells are thrown off. The basal cells are then often small and cubical, staining deeply: they are young cells which have to divide so rapidly to replace the loss that they have not time to reach full maturity. After the elimination of the superficial cells the surface is usually uneven, and this also may be a cause of the stippled appearance seen clinically. Rarely the surface remains smooth. If the desquamation increases it may leave behind only the basement layer of cells, which are then either short and cubical or long and thin. In the latter case they are often set obliquely on Bowman's membrane, owing to the pressure of the lids. Desquamation may go so far as to lead to entire loss of the epithelium."

Following are the reports of two cases which the author observed as showing exfoliation of the epithelium of the cornea and conjunctiva as a complication of dermatitis exfoliativa (arsphenamine).

P. L., white, male, age 39, was Case 1. asymptomatic when he was induced by one of his friends to have his blood tested. The report on the Wassermann test was returned 4+. He received from his friend's doctor three intravenous injections. His family history was negative. In his past history, there was no direct evidence of luetic infection. He had Neisserian infection 15 years before. His pupils were active and there was no indication of any cerebro-spinal system involvement. His epitrochlear and axillary glands were enlarged. Because of this and of his positive Wassermann, he was given June 15th, 1928, an initial dose of .3 gms. neoarsphenamine. Six days later, he received another injection of .3 This was followed in three days by a rash that looked like an urticarial eruption. There was considerable itching. It lasted only a few hours. On June 29th, he was given .45 gms. The same dose was repeated July 6th. On July 13th, .6 gms. were given and repeated July 20th. The itching and eruption had appeared and disappeared a number of times. He had been given also six

doses of 1½ grains of Bichloride intramuscularly between the doses of neoarsphenamine. On July 30th, ten days after the last injection, he became severely ill and hospitalization was necessary. He had a full-blown dermatitis exfoliativa, involving all parts of the integument. The subcutaneous tissues were greatly swollen and very early the cornified layers of the skin began to desquamate first in small pieces and later to come off in quite large plaques.

On August 16th, 1928, when I was called in, I found the patient prostrated with the severe general reaction. The cyclids were swollen shut They were opened with retractors with difficulty Muco purulent material discharged from the conjunctival sac. The conjunctivac, both palpebral and bulbry were greatly congested and arens of exfohation could be defined with fluorescem Smears from the discharge showed many flat epithelial cells, mucous shreds, pus cells and a few

gram positive encapsulated diplococci

The corneae showed areas of irregularity and loss of the epithelium with grevish plaques and peculiar branching figures, very much as are ob served in cases of dendritic keratitis. Fluores cein was taken up irregularly in intensity and the areas stained were colored from a light yellow to a brilliant green. The trides could be seen to be active in response to light.

Treatment was conservative at first Attempt was made by the use of semi saturated magnesium sulphate compresses to reduce the swelling of the lids Later Sodium Bicarbonate solution was used both for cleansing away the discharge and for the compresses Plain white vaseline was applied to the lid margins. The general treatment consisted in complete Sodium Bicarbonate and oatmeal mush baths, with the use of Boric acid ointment. Sodium Thiosulphate was given intravenously.

After two weeks the swelling of the lids had subsided to a great degree with the abatement of the general condition. The conjunctival discharge had in great part stopped, but the involvement of the corneal epithelium remained about the same, affecting three-fourths of the total area in the right eye and two thirds in the left. Photophobia was extreme and it was necessary to keep the eyes closed with dressings.

On August 30th, 1928, the general condition was greatly improved but the corneal condition remained the same and it was decided to make use of a method of treatment which Dr John M Wheeler had used on numerous occasions with great success in cases of recurrent dendritic or filamentous keratitis. It is mentioned very briefly in Fuchs. To insure success, a very definite procedure must be followed out. Dr. Wheeler has kindly agreed to open the discussion and to tell you more about this treatment. In brief, local anesthesia is used, Cocain 2% and Holocain 1%

being employed by instillation The lids are opened with a speculum, and the conjunctival sac gently irrigated. The globe is steaded with fixation forceps and all the diseased or softened corneal epithelium is removed with the curette and with applicators (These should be made by applying a small amount of cotton tightly with collodion and allowing it to dry before being used ) Iodine in 31/2% Tincture is then applied on the tips of tight applicators (no excess) and followed by Alcohol 95% (Ethyl CP) man's membrane where intact remained smooth but where softened or roughened or absent it took the jodine stain. A firm dressing was applied over both eyes. This was changed each 48 After 96 hours, the epithelium of the en tire right cornea had healed over and was per fectly smooth. The left had healed except for a small area about 2mm in diameter in the upper masal quadrant. This resisted all treatment and showed a slight spreading after four weeks, so the operative procedure of removal of the dis eased epithelium was repeated with complete Both corneae have remained healed to date, ten months from the time of the operative removal of the diseased corneal epithelium. He now accepts

OD — 50 Sph — 100 cyl ax 95=20/20— OS — 100 cyl ax 80=20/20—

Case 2, male, white, age 30 years had an atypical primary lesion on the penis in 1918. He had very little specific therapy until June and July 1925, when he complained of incontinence of urme and lightning prins down his legs Wassermann was 4+ and he was given weekly intravenous injections of neo salvarsan, two doses being 45 gms two of 6 gms and three of 75 gms each. He had no previous warning symp. toms of the dermatitis which started one week after the last injections. Itching and tightening sensation back of the ears were first noted, then a rash which quickly spread over the face and neck and arms. After this he went to another physician and later reports indicated that he had suffered a severe course of dermatitis exfoliativa and had had corneal ulcers

He was given no further treatment with any of the arsenicals and was not seen again until June 1927, when he was admitted to Bellevine Hospital with a severe recurrence of the dermatitis exfolitiva. He attributed the outbreak to the enting of tuna fish

In addition to the marked skin signs and symptoms, he had my olyement of the conjunctive and cornea of each eye partly of the same exfoliative nature as his dermatitis and partly due to extropion of the lower lids. There were areas of softening of the corneal epithelium and secondary ulceration.

Conservative treatment was carried on during the worst stage of the condition which lasted

about four weeks. Five weeks after the onset of the condition, the diseased epithelium of the coracae was curetted and treatment applied as in Case 1.

The author saw the patient Sept. 4th, 1928. He had had no recurrence of the dermatitis or keratitis. He complained of poor vision and of the necessity of his squinting and of turning the right eye outwards in order to see. There were irregular superficial and moderately deep corneal opacities with considerable regular and irregular astigmatism. His acceptance was:

There was microscopic evidence of the thinning of the cornea in several areas. The depth of some of the scars indicated that the ulcers which followed the corneal epithelial involvement had been fairly deep in the corneal stroma. The vision was not improved by dilating the pupils. Optical iridectomy was not advised. He was given a partial correction for his astigmatism.

### Discussion

These cases of dermatitis exfoliativa following the administration of the arsenicals come under the class of secondary cases of this disease. They are due to the toxic action of the arsenic which is deposited in the skin and mucous surfaces as an insoluble compound. The Sodium Thiosulphate which was used is said to convert the insoluble arsenic into a soluble form so that it may be excreted. Ormsby<sup>4</sup> classifies Dermatitis Exfoliative as occurring in—

I. Primary Types:

1. Dermatitis Exfoliativa (Wilson)

2. Pityriasis rubra (Hebra)

3. Dermatitis Exfoliativa Neonatorum (Ritter)

4. Dermatitis Exfoliative Epidemica (Savill)

II. Secondary Types:

Due to local application of hydrargyrum, chrysarobin and arnica and possibly also those induced by the internal administration of quinin, arsenic, anti-pyrin and anti-toxin.

The only mention Ormsby makes of the ocular disorder in the primary type is that there is puffiness of the eyelids, and of the fact that the mucous surfaces of the eyes may participate in the general disorder and become the seat of inflammatory and in rare cases even of pseudomembranous and exfoliative processes.

Stokes has gone into the matter of the secondary type following the administration of the arsenicals in cases of lues very thoroughly. He states that the serous and mucous surfaces are involved and obstinate conjunctivitis, stomatitis, etc., usually ensue.

The occurrence of such severe ocular manifestations following the injection of the arsphenamines in the treatment of cases of lues should cause the physician to pause and consider which is more important, the eradication of the systemic infection or the conservation of the vision. After the treatment, certain patients who were asymptomatic from the eye standpoint develop ocular disorders. Some of those with previous luetic manifestations in the eye are made worse or are caused to have recurrences of previous affections.

Zimmerman<sup>7</sup> in 1928, published an exhaustive digest of the literature on this subject. He made no mention of any case such as the two I have described, except perhaps the case of corneal necrosis which ended in perforation.

Zimmerman<sup>7</sup> classifies the ocular reactions which follow the injection of the arsphenamines in cases of lues, into three main groups, the mechanism of which is essentially different.

A. The Group of True Toxic Reactions

1. Conjunctival hyperemia, with which there may be associated palpebral edema. This may be of importance inasmuch as it may portend the occurrence of more severe symptoms if the arsphenamine is repeated or the dose increased. In some cases, this phenomenon may occur as an isolated and recurrent feature without this serious import.

2. Transient Myopia, which has been observed

in a few isolated cases.

3. Retinal and Vitreous Hemorrhages. These may be of grave importance. Warning is given of the use of large doses of the arsphenamines in patients over fifty, or in those with impaired renal function or hypertension.

4. Chorioretinitis and Neuro-retinitis occurbut it is doubtful whether these were true toxic

reactions.

5. Corneal Necrosis. One case of Hegner's was described in which the third injection of neoarsphenamine resulted in a severe dermatitis exfoliativa and death. A severe croupous conjunctivitis with clouding and necrosis of the cornea accompanied the dermatitis and perforation with panophthalmitis due to secondary streptococcus

infection developed.

A similar case was observed in Bellevue Hospital on the service of Dr. John M. Wheeler. / white male, F. P. age 43 years, had had five injections of salvarsan from a private physician at weekly intervals. Following the last one, he developed a severe dermatitis exfoliativa, with conjunctivitis and keratitis which later progressed to a membranous condition of the conjunctiva and the appearance of necrosis of the right cornea with sloughing and perforation. Secondary infection followed and it was necessary to eviscerate the right eye. The patient received Sodium Thiosulphate intravenously and recovered generally in due time. The lesions of the left eye

healed without complication as the cornea was not involved

#### B Heryheimer Reactions

A Hersheimer reaction may manifest itself as an intensification of an active lesion, as an activation of a quiescent lesion or as an un expected appearance of changes in structures clinically negative. The theoretical cause of this reaction is the sudden liberation of toxins from the killed organisms or from an increase in the activity of the spirochaetes just before their destruction.

These manifestations are most common in inflammations of the uveal tract, less common in the corneal affections. They seldom cause any permanent damage to the visual function. But if an optic neuritis is produced or made worse the results may be disastrons. Therefore, in any case, where the optic nerve is involved, great caution must be exercised.

Uzetts a Intensification of an acute mido cyclitis is frequent. It becomes evident by an increase in the vascular reaction, production of hyphoemi, an increase in the floaters and albumin content of the aqueous and in the deposits on the endothehum. b Activation of an old quiescent uvents is rare c. It is uncommon for an indo cyclitis to appear in an eye otherwise normal Occasionally where for example the optic nerves have been affected, a fresh chorio retinitis may supervene after salvarsan.

Keratitis Reactions in Interstitial Keratitis are rare. The lesion runs its course in spite of intensive treatment.

Optic Neuritis There have been cases of sud den blindness in pitients with optic neuritis fol lowing the injection of the arsphenamine. No more was given and the vision returned following the use of the mercurials. In all cases of optic neuritis, anti-luctic therapy must be instituted with caution. A preliminary course of bismuth or mercury should be used, and then the first does of the arsphenamines should be small.

Tabelic Optic Nerve Atrophy Disastrous results may be produced in these cases Transitory reactions in the torm of flashes of light for 24 hours following the injection occur at times Other evidence such as temporary loss of vision indicates the irritation of the optic nerve by the arsenicals

We all have heard of cases where the vision was little affected in tabes and where practically complete amairosis developed within six weeks or two months after intra spinous Swift-Ellis treatments

Ophthalmoplegias Rare as an untoward reaction Paralysis of accommodation has been reported

C Nuero - Recurrences and Irido - Recurrences 7

Ocular Lesions following Insufficient Treatment of Primary or Secondary Lues with the Arsphenamines

Really an expression of the effective action of the drugs. The body in the early stages of the disease has not had time to develop immunity and most of the spirochaetre are killed off but later when the remainder have multiplied again, they encounter a defenseless host and affect chiefly the uvea, optic nerve and nerves to the extrinsic ocular muscles.

In analyzing these lesions, the following features are noteworthy

1 The development of the ocular lesion in patients treated some time previously for early syphilis

2 Severity of the reaction with absence of response to anti syphilities

3 Extensiveness of the lesions

4 The degree of the exudative reaction, syphilomata being produced

5 The absence of complement in two pa tients in whom the Wassermann test was performed

The condition evidently represents a suppression of early syphilis with reduction or disappearance of the complement fixation bodies from the blood stream followed by a marked exudative reaction at the site of the surviving spirochaetae

These occurrences in no way reflect on the therapeutic value of the arsphenamines. They really express the marked efficiency of the drug and point to the necessity of the continuance of treatment even after the abatement of the symptoms in order to clear up the infection. The prophylaxis of such lesions depends on the intensive, prolonged and systematic treatment of the early lues.

It is well that an exact analysis of the ocular complication and its sequelae in these cases be made so that efforts may best be directed toward conservation of vision

I he essential pathology of the ocular disorder in the two cases observed was that of exfoliation of the epithelium of the cornea and conjunctiva with secondary changes which followed upon its imperfect healing. The terms Keratitis and Conjunctivitis Exfoliativa seem to be descriptive and suitable for the condition. They are expressive also of the analogy which exists between this complicating feature and the general dermatitis.

During the acute stage, conservative treat ment was certainly indicated as the operative measures which gave success later would have failed had they been used too ertly. Stokes warns of the dangers of any general surgical intervention in the acute stage as for example any interference with focal infections. It is very doubtful whether the corneal com

plication and its sequelae would have cleared spontaneously as the lesions had become chronic in both cases and the obstinate nature of dendritic and filamentous keratitis from other causes is well known. The prompt healing which followed the surgical removal of the diseased epithelium of the cornea proved the worth of this procedure in these cases as it has in dendritic and filamentous keratitis from other causes.

This treatment is mentioned briefly in Fuchs<sup>6</sup> (Duane) as follows: "Erosions are best treated by applying a simple protective dressing which should be continued until the epithelium has regenerated. If in spite of this, relapses occur, we obtain solid union of the epithelium to the cornea and hence also a cure, if we scrape off the epithelium wherever it is but loosely adherent to the cornea and then paint this area with tincture of iodine or saturated aqueous solution of chlorine."

The value of Doctor Wheeler's contribution in this matter is in the development of an exact technique by which the success of the pro-

cedure may be assured.

## Summary and Conclusion.

There is evidence that the superficial cells of the epithelium of the cornea and conjunctiva normally exfoliate and are replaced by cells which have developed from the deeper layers.

In certain abnormal states, there is pathological exfoliation of these cells to greater or lesser degree. In some diseases of the eye, this process is a principal feature. This pathological exfoliation often produces secondary disturbances which are important.

Cases of dermatitis exfoliativa secondary to arsphenamine poisoning have been observed in which the terms Keratitis and Conjunctivitis Exfoliativa seemed to be descriptive and appropriate for the ocular complication in this disease.

The occurrence of severe ocular reactions in cases of lues following the use of the arsphenamines should often cause the ophthalmologist and syphilologist to pause and consider which is more important, the conservation of vision or the elimination of the luetic infection.

Removal of the diseased epithelium with the curette and the application of Iodine and Alcohol in the manner described led to the removal of the secondary changes following the exfoliation of the corneal epithelium in the cases described and caused prompt and complete healing of the corneal lesions.

### PRESIDENTIAL GREETINGS

A study of the activities of organized medicine in New York State shows that there has been a considerable advance this year in modernizing professional relationships and public social needs The evolution in preventive medical knowledge is being made a part of the practice of medicine as rapidly as conservative, scientific judgment permits Practical efforts to advance organization for the better administration of public health have become more definitely a part of the policy

of organized medicine. The solution of outstand ing professional problems in social needs has been advanced. Graduate Education is solving other professional problems. It is aiding in the reinstatement of the family physician in public estimation. There is a better recognition of the fact that the family doctor is the key man in preventive medical practice. He is familiar with his people. He has knowledge of such important things as hereditary deficiencies. His personal

relationship and his personal responsibility to his families make him the most valuable factor in the final distribution of public health practice. The healing art is the greatest factor in human betterment. It is worthy of the utmost attention and the most careful consideration of all its relationships. The medical profession has today a broad vision of social needs and a fair understanding of the economic changes in our national life and their influence on social problems. It understands better than it did, even a year ago, the new conditions confronting the medical profession and the official, unofficial and welfare agencies. The medical profession appreciates more than ever before that there are many fac-

722

tors entering into the betterment of public health and that each one should clearly understand its limitations, its relationships and its responsibilities

So far as lies within my power, I shall try to advance during my administration the present activities of organized medicine, and to meet new problems and new conditions that may arise in the relationship of the medical profession to other health agencies, and to the State. I should like to be able to show that there is more than medicine in a doctor's life, and that the profession may exert by proper leadership an influence in human betterment beyond our present realization.

W. H. Ross.

## PRESIDENTIAL LEADERSHIP

It is a fundamental principle in embryology that each individual repeates the story of the evolu-

Or. William Hugh Ross, President of the Medical Society of the State of New York.

tion of the race or group. The present activities of the Medical Society of the State of New York

A STATE OF THE STA

have been an evolution from small beginnings. First came the ideals of a few leaders who, a half-century or century ago, had visions of a medical service which failed to materialize because physicians did not possess the scientific knowledge, nor the people the civic consciousness to transmute the ideals into concrete forms in the everyday practice of medicine. both the medical profession and the public are beginning to see the realization of the ideal of an efficient partnership in the giving and the receiving of medical service, and of joint responsibility for the health of all persons in a community. Medical service always requires cooperation between the physician and the patient. Modern medical service also requires the cooperative action of physicians as a group or medical society with the people represented by governmental departments and volunteer health organizations.

The story of the medical life of Dr. William Hugh Ross, the new President of the Medical Society of the State of New York, epitomizes the evolution of modern medical service. The only physician in a small rural community, for over forty years, he was also the leader in all other community activities - business, social, civic, moral and religious. His sphere of influence extended in ever widening circles until it embraced all of Suffolk County, then Long Island, and finally the State; but always he was the medical practitioner interpreting the point of view of the family physician to all other civic groups. This, too, has been the object of the activities of the Medical Society of the State of New York, and to them our new President may truthfully apply the words of Milton-"All of which I saw, and much of which I was"

### RESPONSIBILITY FOR MEDICAL LEADERSHIP

The history of a country is predominantly biographical, and the story of a medical society centers around one or two men. Dr. Sadlier, churman of the Committee on Public Relations, has often said that the great problem of the committee is to help each county society to discover the "key man," who will personify the medical profession in the discharge of the civic duties which devolve upon the practising physicians of a community

One of the greatest problems before physicians is that of arousing a sense of civic consciousness in the breast of every doctor, beginning with graduite education in surgery, medicine, and the common specialties, broadening into the fields of prevention, and extending to office holders and

other leaders in civic progress

Medical leaders here and there have studied the entire field of medical practice and have developed solutions of their problems in their own small communities, and they have used their experience to devise lines of action which will

apply to all other communities

Just as the practice of bedside medicine and surgery is the same throughout the world, so the methods of the practice of civice medicine are universal. It has been the good fortune of the leaders of the Medical Society of the State of New York to devise practical methods by which the physicians of every community may discharge their civic duties to the great advantage of themselves as well as of the people, for what ever helps the people, helps the doctor. Medical service in any community is an evolution which begins in the experiences of those who must give the service. It cannot be dropped upon

either the doctors or the people. It must begin as a small seed planted and nurtured by a local physician who understands both his medical brethren and his people. His duty is largely educative, but also to an even greater extent in spirative His example will speak louder than his The members of every county medical society possess the cold knowledge of how to discharge their civic duties The older books on mental philosophy divided mental processes into the intellect or knowledge, the sensibilities or emotion and feeling, and the will, or action Committees of the State Medical Society have developed and published principles of action which have reached all the members of County Societies But knowledge alone does not arouse emotion or produce action

The stage of emotion and feeling was reached some five years ago, and now local leaders are becoming interested in the application of the newer knowledge of medical practice. The progress in interest seems remarkable to those who remember the antagonisms which these newer principles

aroused when they were first stated

Already there are tangible evidences that phy sicians are entering upon the third stage of activity, that of action. Two counties, for example, established county departments of health during the past year, and physicians are making periodic health examinations in increasing number.

The leaven of personal leadership in medical civies is working throughout New York State but leadership will always test upon a few who will surely rise up as knowledge is transformed into inspiration and action

### LOOKING BACKWARD

### This Journal Twenty-Five Years Ago

Milk Commission for Rockland County Rockland County has always had medical lead ers who have secured advanced action in public health by the County Medical Society. This Journal of June, 1905, contains the following description of the establishment of a Milk Commission in Rockland County.

"The Rockland County Milk Commission was formed at New City on Wednesday, for the purpose of looking after the milk supply in this county and seeing that the milk is fur inshed under more sanitary conditions than in the past. The health officers of the different towns in the county were requested to meet with the members of the Rockland County Medical Association at this time, and Orangetown, Clarkstown and Haverstraw responded, but Ramapo and Stony Point were not represented

"Those present at the meeting were Dr G A Leitner president of the County Medical Association, Dr Crosby Haverstraw secre

tary of the County Medical Association, Dr C D Kline, Nyack health officer, Dr Carter, health officer of Haverstraw Dr J W Giles, South Nyack health officer, Dr N B Bayley, of Haverstraw, Dr S W S Toms, of Nyack, and a representative from Clarkstown The milk commission was formed, with Dr Leitner as president and Dr Crosby as secretary and its object is to recommend to boards of health that they adopt regulations controlling the milk supply of Rockland County and issuing licenses to milk dealers and yenders

"The Health Commissioner of New York City Dr Thomas Darlington, said he is in hearty sympathy with the formation of the Rockland County Milk Commission for the maintenance of sanitary conditions on the premises of milk producers. He also hopes to see other counties in this and neighboring States take the same public interest that Rock.

land County has taken"

## MEDICAL PROGRESS

Auricular Flutter Following Direct Injury to the Chest.-Although the effects of direct injury to the chest have been recorded in a number of contributions to the literature, the case described by Morris H. Kahn (American Journal of the Medical Sciences, May, 1930, classis, 5), is the the first in which auricular flutter has been produced by such an injury. The patient was a robust porter, who had always been in good health. While holding down and leaning over the handle of a crowbar under a heavy soda fountain, the handle recoiled, striking him twice sharply against the lower left breast region. He screamed with pain but did not become unconscious. When first seen by the writer, three weeks after the injury, he was found to be suffering from auricular flutter. The electrocardiogram showed left ventricular preponderance. There was an inconstant ventricular rate of 75 to 80 per minute. The auricular rate was 300 per minute with distinct waves of auricular flutter in Leads II and III. The patient died four months after the accident. As there were no other causes which might induce auricular flutter, it may be assumed that it was due to the accident. The pathogenesis can only be surmised, as no autopsy was permitted. However, the possibility of subepicardial ecchymosis in the auricular muscle is to be considered. The blood pressure findings in the case—a distinct pulsus alternans with a difference of 30 mm. in the systolic pressure between alternate cycles—suggests that the auricular function in producing ventricular filling is a most important one. Apparently every contraction of the auricle during flutter contributed its definite measure of blood to the ventricular volume.

Treatment of Heart Block with Adrenalin and Ephetonin. G. W. Parade and K. Voit remind us that heart block often ends fatally and that our resources for its treatment are uncertain; so that the chief aim of the physician is to prevent new attacks. The authors have succeeded in stopping attacks, both primary and consecutive, by the use of the two substances mentioned. They were not of course the first to make use of adrenalin, for scattered case reports are on record in which it was employed with success. When the paper was prepared the authors were unaware that ephetonin had also been employed, but have since found three papers in the American Heart Journal, in which the two drugs were exhibited with the addition of a third-barium chloride. The re-

sults were excellent, but it was doubtful whether or not the barium was responsible for The authors report a single case, of typical heart block with numerous recurrent Thyroxin, digitalis, and caffeine attacks. proved inert. Finally a seizure seemed to indicate impending death, no radial pulse, heart beat only 12 per minute. Adrenalin as a cardiac stimulant proved marvelously efficacious for the moment, but it was necessary to inject it at very frequent intervals and hence the thought to test ephetonin which maintained the good result. The patient continues to take two tablets daily and apparently the drug has not been withdrawn yet for fear of recurrence. Credit for the idea came originally in part from Wenckebach who believed on theoretical grounds that a combination of ephetonin and barium chloride would control heart block. This was in 1927, but apparently two Americans, Levine and Matton, anticipated the Vienna internist by a year by actually prescribing an association of adrenalin, ephetonin, and barium chloride. In 1928, another American, Stecher, seems to have shown that the barium salt can be dispensed with .- Deutsche medizinische Wochenschrift, Feb. 1, 1929.

The Nature and Treatment of Cardiac Failure.—Tinsley Randolph Harrison, J. Alfred Calhoun, and Cobb Pilcher state that the recognized causes of cardiac failure are not sufficient to explain the clinical phenomena. They have analyzed skeletal and cardiac muscle in patients dying of congestive heart failure and in individuals dying from other causes with the finding that the potassium content of muscular tissue in those dying from congestive They have found heart failure is decreased. reason to believe that edema is not the effect but the cause of the loss of potassium. In an analysis of the skeletal muscle of living patients before and after they had lost large amounts of edema, it was found that as edema decreased the amount of potassium in the muscle increased. It was also shown that the potassium content was low in edematous muscles when taken from patients whose edema was not of cardiac origin. The conclusion, therefore, seems justifiable that loss of potassium from the heart muscle and consequent deficiency of buffering power may be an important factor in the production of cardiac fatigue, and this phenomenon appears to be a result of edema. If this be true, cardiac fatigue is originally a result of cardiac insufficiency Congestive failure originally occurs as the result of cardiac overwork or of myocardial disease or of both Once edema has developed, the heart muscle begins to lose its alkali and with each successive "break becomes more depleted, and even though the load may be di minished the vicious circle continues. The au thors have attempted to alleviate the condition in some measure by the administration of potassium salts with seemingly encouraging results Seven cases are reported in which the prognosis seemed to be very poor With the administration of dibasic potassium phosphate five of them progressed much more favorably than they had previously done. The cases are too few however to warrant definite conclusions - Southern Medical Journal May, 1930, хаш, 5

The Preservation of a Healthy and Efficient Circulatory System from Childhood to Advanced Age - James Barr emphasizes that a clear and comprehensive knowledge of diseases of the respiratory and circulatory systems must be based on a good conception of physics also points to the importance of hereditary influences on the circulatory and endocrine sys We should get children with healthy circulatory systems and should know how to keep them so Large numbers of children suffer from defective function of the thyroid gland In Nature's imperfect attempt to rem edy the defect we get increased growth of lym phoid tissue, adenoids, large tonsils, and sub sequent infections, such as rheumatic fever. In these cases there is a defective supply of iodine with lessened calcium metabolism and an accumulation of lime salts in the tissues Acute rheumatism occurs more frequently among children who have a liberal supply of milk. In this disease milk should be cut out of the diet, and potassium and sodium salts and of course, the salicylates should be given I he blood pressure should be kept low by rest and heart tonics, such as digitalis, should be avoided Barr discusses the important role of calcium metabolism in relation to degenerative changes in the circulatory system. The fixed lime, or that linked to the molecules of albumin, increases the viscosity of the blood while the free cylcium ions in association with the suprarenal and pituitary secretions increase the tone of contraction of arteries and arterioles, raise blood pressure and improve the force and efficiency of the cardiac contractions. Under the use of phosphoric acid Barr has seen free calcium ions increase, while coarse valvular murmurs abated, and in some cases disappeared The best way to lessen and prevent degenera tive changes is to maintain a low systolic and a high diastolic pressure. Barr has found use-

ful a combination of calcium iodide, potassium chloride, and tincture of jodine, supplemented by thyroid Persons with a slow infrequent pulse will find it an advantage to cut down the lime salts and take small doses of jodine and thyroid If a person is in a dead frint one should not wait for the pace maker to start the heart but raise the lower extremities so as to increase intracardiac pressure in the right auricle and ventricle. This is the best cardiac When appea is established from excess of oxygen and deficient carbonic acidwhich is the natural stimulant to the respira tory center-the worst method of treatment is artificial respiration. In many diseases the free administration of oxygen establishes a partial apnea and deprives the heart of the as sistance of the respiratory pump. An excellent respiratory stimulant is to play a stream of cold air on the patient's face In auricular fibrillation there is always a deficiency of cal-Ringer's solution which contains about double the usual amount of calcium should be drunk freely. An attack of fibrillation may be arrested by eliciting Abrams cardiac reflex of contraction repeatedly until the heart is well charged with calcium -British Medical Journal. April 26 1930 1 3616

725

The Treatment of Constipation in Children by the Use of a Residue-free Diet - Richard M Smith states that the treatment of children with chronic constinution, due to disturbed function of the colon dependent upon a distorted anatomical structure, which can usually be demonstrated by barrum enema studies is most effective if directed toward a restoration of a normal condition of the colon which has a large cellulose residue tends to make the condition worse, for it increases the bulk of material which may be retained as hard masses or adherent to the mucous membrane of the colon The aim should be to reduce the tecal residue to a minimum in order that the colon may be completely emptied done by excluding all roughage from the diet Vegetables cereals and fruit must be strained through a fine sieve. No coarse breads are allowed. In some cases milk should be restricted or excluded, as it may produce considerable With this diet the colon is not distended and the stools become smaller in size In order that the fecal residue may easily pass forward in the colon, mineral oil is liberally administered. It is given in small doses ifter each meal, rather than in single large doses The dosage will vary, but one half to one ter spoonful three times a day is usually adequate To assist the colon in exacuating, some from of catharsis is usually necessary as a temporary measure preferably castor oil weekly onefourth to one half ounce at bed time

mata may be necessary during the first few weeks of treatment, but should be given in accordance with careful directions in order not to distend the colon. Plain soapsuds are employed, preferably in the evening. The enemata should be abandoned as soon as possible. The interval between doses of castor oil may be lengthened, and the drug discontinued as soon as regular satisfactory movements are established. It is well to ascertain the condition of the colon at this time and to be guided by the findings in the gradual return to a full diet. With the cure of the constipation, the other symptoms of pain, vomiting, and easy fatigue disappear .- New England Journal of Medicine, April 24, 1930, ccii, 17.

Cisterna Magna Pressure Syndrome.—Mark S. Reuben and Iulius Chasnoff have observed in certain cases of meningitis a syndrome characterized by rapid pulse, rapid respiration, high or low temperature, and occasionally delirium. When these symptoms persisted for seven days the termination was always fatal. In a case of meningitis, about two years ago, they decided to puncture the cisterna magna for the purpose of administering antimeningococcus serum. After the puncture was made it was discovered that through an error diphtheria serum had been sent instead of antimeningococcus serum. About 25 cc. of spinal fluid was removed and no serum was introduced. Within a half hour there was a marked improvement in the patient's condition, the sensorium cleared and the other symptoms gradually subsided. Four similar cases are cited, in three of which recovery followed puncture of the cisterna magna. On the basis of observations made in these and other cases the conclusion is reached that the syndrome may be due to pressure on the medulla and pons by a distended cisterna. In such cases cisternal tap produces immediate improvement in the general condition. At the first tap no serum is introduced, regardless of the character of the fluid. In several cases there was no further need of tapping. The symptoms are usually due to pressure and not to infection or toxemia. If there is a return of symptoms, another tap should be performed, and if the fluid withdrawn is turbid and if previous examination has revealed organisms, serum should be introduced, but no more than onehalf the amount of fluid withdrawn. This procedure should be carried out even if fluid can be obtained from lumbar puncture, when the syndrome above described is present. In these cases the cisterna is apparently not in direct communication with the rest of the subarachnoid space, so that spinal tapping does not relieve a disturbed cisterna. If this syndrome be allowed to continue without relief for seven days, the outcome is always fatal.—Archives of Pediatrics, April, 1930, xlvii, 4.

Swelling of the Feet and Ankles not Associated with Albuminuria or Gross Organic Disease.—A. Arnold Osman describes a type of edema without albuminuria, which is quite commonly met with in debilitated women, though occasionally it is seen in debilitated men and even in children. It cannot be ascribed to the anemias, chlorosis, war edema, starvation edema, beriberi, or varicose veins of the legs.. It has been shown that "debility" is a state which is generally associated with acidosis. This underlying "acidosis," the exact nature of which is not known, leads to excess of water in the tissues, and in minor degrees of the disorder the accumulation of fluid is only sufficiently great to attract attention under the influence of gravity; hence the frequency with which it apparently occurs in the feet and ankles alone. There is usually a considerable diminution of the plasma bicarbonate values in these waterlogged patients, which is probably not due to hydremia, as then the hemoglobin percentage would also be reduced. However, it is possible to have a normal plasma bicarbonate at the same time as a true Furthermore, a normal reaction in the blood does not necessarily preclude an abnormal reaction in the tissues. On this theory of pathogenesis patients have been treated simply by giving 30 grains each of potassium citrate and sodium bicarbonate with 30 minims of syrupus aurantii in an ounce and a half of water, increasing the number of doses per day according to the need. It may be necessary to give as much as 600 or 700 grains a day or more. It is probably wise to limit the intake of fluid to three or four pints a day.' No other dietetic restrictions appear to be necessary. No untoward symptoms have been noted that could be ascribed to the treatment.—British Medical Journal, April 26, 1930, i, 3616.

Tonsillectomy by Diathermy under Surface Anesthesia.—After pointing out the disadvantages of the usual methods of tonsillectomyblunt dissection, the x-rays or radium, and the electrocautery-Warner Collins describes the technique of tonsillectomy by the use of diathermy which he has evolved as the result of observations on more than 150 adult patients. He does not think the method so suitable for children under the age of 14 years, since to them a general anesthetic is not as alarming as the appearance of electrical apparatus. older patients no general anesthetic is required. It is sufficient to spray the throat with not more than 2 grains of cocaine hydrochloride dissolved in 2 drachms of water. The tonsillar electrode is usually a small metal ball mounted

on a curved insulated handle. An indifferent electrode, consisting of a thin sheet of lead, 8 by 4 inches, and covered by four thicknesses of plain lint saturated in 20 per cent, salt solution, is strapped to one wrist and bears a large diathermy terminal. A diathermy current of 2 amperes is applied, which rapidly causes a rise of temperature in the tonsil to 100° C. The tonsil soon shows, radiating from the center of the active ball electrode, a zone coagulated tissue, which rapidly desiccates. Complete destruction of the tonsil is effected slightly beyond this area of coagulation. The whole process lasts only a few seconds, after which the active electrode is "arc'd" a few times from the surface of the tonsil in order to seal any vessels. Occasionally, it is advisable to complete the tonsillectomy in two, or very rarely three, stages. The patient is invariably seen at the end of a month, and again after three months. Should a fragment of lymphoid tissue have escaped, it is removed at this stage. It is not necessary to hospitalize the patient. An antiseptic mouth wash is ordered to be used after meals, but gargling is absolutely forbidden. The sloughing process is usually complete at the end of ten days or a fortnight. No secondary hemorrhage has occurred. The author believes that this method possesses at least all the advantages of other methods, and none of their disadvantages,-The Lancet, April 19, 1930, i, 5564.

The Treatment of Pneumonia.-Shortly before his death Schwalbe, editor of the Deutsche medizinische Wochenschrift, sent out a questionnaire on the serum treatment of pneumonia, some of the replies to which are summarized in the issue of the journal mentioned for April 4, 1930. v. Krehl of Heidelberg had previously reported a number of cases, many of them very satisfactory in their results, but had treated only two since then. Both of these patients recovered promptly, although one was a confirmed alcoholic. H. Sahli of Bern had formerly made a considerable trial of serotherapy, but with not very satisfactory results, and had now abandoned it, for the reason that he could see no advantage in waiting to make mouse experiments before giving his patients the benefit of early treatment. He had obtained excellent results with optochin in doses of 4 grains three times a day. G. v. Bergmann of Berlin had had no experience with the scrum treatment, being entirely satisfied with intramuscular injections of quinine. Early treatment of pneumonia, he said, was of the greatest importance, but much precious time was lost while typing the diplococci. Morawitz of Leipzig had treated about one hundred cases of pneumonia during the winter of 1928-29. The polyvalent serum was given

intramuscularly, never intravenously, and influenza serum was also used. His impression was that serotherapy was serviceable, for some of his cases, in which he had made a very unfavorable prognosis, went on to a prompt recovery. Schittenhelm of Kiel had resorted to serum therapy in many cases, but could never convince himself that there was much to be gained by it. One great and insuperable objection to the method was that it called for typing the pneumococci, which was a timedestroying process. Volhard of Frankfurt-am-Main had treated upward of 50 cases, nearly half with monovalent serum, the others-more advanced cases-with polyvalent serum. spite of having given large doses the author could not persuade himself that this method had any advantages over the therapeutic measures more commonly used in Germany. The fever sometimes fell promptly, but the pulse remained high and the temperature rose again. When recovery occurred, it was usually by lysis. Zinn of Berlin had treated a number of typed cases (mostly II) with serum and had had several severe cases of anaphylactic shock, though fortunately none fatal. He was not enthusiastic in his praise of serotherapy, but thought that, in view of the American reports and the favorable reports from the Heidelberg Clinic, further trial of the method was desirable. A number of others reported that they had had little or no experience with the serum treatment of pneumonia, and many among them said that they had found the quinine treatment so satisfactory that they saw no reason to experiment with any other method.

Halogen Salts of Magnesium in Prostatic Subjects .- Stora has been experimenting with the halogen salts of magnesium in a variety of conditions and often with happy resultsfor example in spasmodic asthma. In the present communication he reports a few cases of urinary troubles in prostatic subjects and gives four case histories which speak for themselves. In general he finds two groups of patients, one with nocturnal pollakiuria alone, while in the other there is also diurnal pollakiuria with slow and labored evacuation or some impairment of the general health. In all of the patients some enlargement of the prostate was found. Improvement was rapid and not only were the symptoms improved but the prostate underwent a notable reduction in size, and when the general health was involved there was also improvement here. The author would have liked to note the effect on the residual urine but the patients were of the type which refuse catheterization as unnecessary because of the absence of actual obstruction. -Bulletin de l'Académie de Médicine, March 18, 1930.

## LEGAL

## OUR GROUP PLAN—A PHYSICIAN'S CLAIM FOR REIMBURSE-MENT EXAMINED AND DISALLOWED

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

Our group plan of indemnity against actions for malpractice has been in operation for nearly a decade. Its success is an established fact. Its benefits have been recognized by a large majority of the members of the Society who have taken advantage of it through individual participation.

Your Committee on Insurance, consisting of Dr. John A. Card as Chairman and Dr. Charles Gordon Heyd, has sought in every way to bring home to the members of our Society the desirability of our group plan. The members of this Committee have given unsparingly of their time, energy and talents in going throughout the State explaining to the members of the various County Societies the workings of our group plan.

It cannot be too often stated nor too strongly stressed that the plan is operated for the benefit of all, and hence individual policy-holders should realize that only proper expenditures should be charged against the experience of the group plan.

A few months ago, a matter came before your Insurance Committee and Executive Committee for decision. These Committees, because of the importance of the question involved, requested your counsel to prepare and present in our State Journal a brief résumé of the case in question.

A physician holding a policy in our group plan, while treating a patient, broke off a needle. He immediately had an r-ray picture taken, located the needle and removed the patient to a hospital where he secured the services of another physician who extracted the needle. The doctor then presented a hospital bill for \$15, and a bill for the surgeon who removed the needle in the sum of \$150, to Mr. Harry F. Wanvig, the authorized indemnity representative of the Society, claiming that these bills should be paid by the insurance company. Mr. Wanvig told the doc-

tor that he did not believe these bills constituted a proper charge against our group insurance, and referred the matter to our office.

The doctor then communicated with your counsel, and he was told that the claim was not a proper one inasmuch as in removing the needle the doctor was only doing that which it was his duty to do as a physician. The doctor in question, however, obtained a general release from the patient and forwarded it to your counsel with a demand that the matter be referred to the insurance carrier. At this point it should, be stated that at no time was there any claim or suit for malpractice brought or threatened by the patient in connection with the breaking of this The doctor further told your counsel that the surgeon who removed the needle was not pressing for his bill but that he, the doctor, was desirous of seeing that the surgeon was paid. In this conversation your counsel was further authorized by the doctor to reduce the surgeon's bill to the sum of \$75.

We took the matter up with a representative of the insurance company, who requested your counsel to submit the matter to the Insurance Committee and the Executive Committee for decision, stating that the approval of the Insurance Committee and the Executive Committee is at all times "a prerequisite for the successful conduct of our entire relationship with the New York State Medical Society." Your counsel duly submitted all the facts to the Insurance Committee who, after due consideration, reported to the Executive Committee that the doctor's claim be disallowed. This report was unanimously adopted and approved by the Executive Committee, and your counsel promptly notified the doctor in question of the decision of these Committees on his claim.

# CLAIMED INJURIES RECEIVED DURING CLAIMED NEGLIGENCE IN CONFINEMENT

In this case the plaintiff consulted the defendant-physician for her condition of pregnancy and made arrangements with the defendant to take care of her confinement and to render the requisite prenatal and after care. Arrangements were made for the delivery to

take place in a private sanitarium, and for a weekly examination until the date of delivery.

On the day prior to the delivery the plaintiff was admitted to the private sanitarium. After being in labor for some time, the plaintiff having been given an opportunity to deliver herself normally, it was finally determined to use forceps. The delivery was, however, effected without any unusual degree of force, both mother and child having an uncventful recovery. They were discharged from the san itarium and from the doctor's care two weeks from the date of delivery.

About ten days thereafter, the defendant physician was requested to call it the patient's home, where he was advised that the mother had severe abdominal cramps. After a thorough examination a tentative diagnosis of gall stones was made and an operation advised Since the defendant, however, did not perform such operations, he recommended that a sur geon be called in consultation

It appears that thereafter the patient was operated upon by a surgeon for pancreaturs. Shortly after this latter operation, the plaintiff commenced an action against the physician who had taken charge of her confinement, contending that the physician had been negligent in his care, in that he permitted her to remain

in labor too long during which period he made no examination and gave her no treatment. that no measures were taken to hasten the time of delivery when the plaintiff was in labor, and that no measures were taken to relieve the plaintiff's condition after delivery, that as a result thereof the plaintiff contended that she suffered certain injuries among which were that she contracted a condition of acute pan creatitis due to a septic inflamination of the principals, that she lost her voice for a considerable period of time and that in the fol lowing three years she had not fully recovered her voice, that her speech was permanently af feeted that she had lost a great deal of hair, that she had sustained a great many cuts and bruises on her abdomen and that her sight had become greatly impaired all due to the claimed neglect of the attending obstetrician. The action, however, after having been pending for a period of three and one half years was finally dismissed without a trial thereby terminating the proceeding in the doctor's favor

### DEATH CLAIMED DUE TO MUSTARD BATH

In this case the doctor was cilled to the home of plaintiff's deceased and upon arriving was advised that the patient, two years old, had fallen into a tub of hot soapsuds. Upon examination the doctor found second and third degree burns of the back, thighs, lower limbs and scrotum, and advised that the patient be sent to a hospital, which was refused by the infant's mother. An opiate was administered, bicarbonate of sodapaste applied, and the patient wrapped in sheeting coated with this paste.

Sometime after the doctor left, he was asked to return Upon his return he found the child in convulsions. Ether, chloroform and morphine were successively administered in an attempt to restore the child, all of which failed. The doctor then prepared a mustard bath, and another physician was sent for to aid in the treatment. The patient's feet were then immersed in the mustard bath, only the unburned portions of the lower extremutes being intermittently immersed. While the mustard bath was being administered, an injection of bromide and chloral was given by rectum.

During the course of giving the mustard bith, an ambulince from a hospital arrived and the child was taken to the hospital before it came out of the convulsions. The child died the same night at the hospital. An autopsy was performed, and the cause of death given as shock due to second degree burns of the entire body, buttocks, torso and thighs.

Thereafter an action was commenced against the first physician, on the ground that it was improper to administer a mustard bath for the purpose for which the mustard bath had been given, and that as a result of the giving of the mustard bath the infant died. It was also contended that at the time of giving the mustard bath the entire body, including the burned areas. was immersed in the mustard both which contention was however successfully refuted at the time of trial This action duly came on for trial, and at the close of the plaintiff's case the defend ant's motion to dismiss the complaint was granted, thereby making it unnecessary to put on any evidence for the purpose of the defense and terminating the action in the doctor's favor

## CLAIMED WRONG DIAGNOSIS OF ECTOPIC PREGNANCY

In this case the defendant-physician was called to the home of the plaintiff and found the plaintiff in bed. He received a history that she had passed her period several weeks and had pains in the abdomen. A vaginal examination was made which revealed bleeding from the vagina and an enlarged and boggy uterus. The patient stated that she had been using hot douches. The doctor prescribed resting in bed and called again the following day, at which time the patient continued to complain of pain and bleeding.

Arrangements were made for a diagnostic curretage, which was performed on the following day, under a general anaesthetic. Small pieces of tissue were removed from the uterus with the aid of a dull currette. The patient remained in the hospital for about one week when she was permitted to go home.

She continued to complain of abdominal pains and also rectal pains. A rectal examination proved negative. A physician specializing in obstetrics and gynecology was called in consultation and made a diagnosis of inflammation of the uterus and ectopic pregnancy was

suspected. Continued rest in bed was prescribed with applications of a hot water bag to the abdomen.

During the next three weeks the patient went to another hospital, but later returned home and again consulted the defendant. After a period of three weeks from the date when the specialist in obstetrics and gynecology had been called in, he was again called. At this time he confirmed his diagnosis of a mass in Arrangements were the left fallopian tube. made for the patient to be admitted to the hospital where an abdominal operation was performed and an ectopic condition revealed. The ectopic condition was cleared away, the abdomen closed, and the patient remained in the hospital for a few weeks, making an uneventful recovery.

About one year thereafter, the patient instituted an action against the family physician, alleging that he negligently failed to properly diagnose her ailments. The action, however, never came to trial and was duly dismissed, thereby terminating the proceeding in the doctor's favor without trial.

## CLAIMED NEGLIGENCE IN CAUSING BURN DURING HERNIA OPERATION

In this case the plaintiff consulted the defendant-physician, who after examination made a diagnosis of left inguinal hernia and suggested an operation. Ten days thereafter the plaintiff entered the hospital and on the following day a typical Ferguson-Andrews operation was performed which was completely successful. The patient came out of the ether satisfactorily and was seen daily by the attending physician. The patient remained in the hospital for a period of fifteen days after the operation.

On the second day after the operation, it was noticed that the patient had a red spot on the lower portion of his back which simulated a first degree burn or erythema. The attending physician's attention was called to the condition and he directed that sterile gauze dressings and cold cream be applied. The condition spread down to the buttock and thighs causing the patient pain. However, by the time he was ready to leave the hospital the condition had cleared up. There was no sloughing

and the patient's back was entirely normal at the time of his discharge from the hospital. He called at the doctor's office on two occasions subsequent to leaving the hospital, at none of which times did he make any complaint.

Several months thereafter, however, without notice of any kind he commenced an action against both the attending physician and the hospital where he had been treated. In the complaint the plaintiff charged that during the performance of the operation, and while the patient was under the effects of a general anæsthesia the plaintiff sustained severe burns to the buttock, back and thighs. It was, however, established that the patient had perspired profusely immediately following the operation and since the patient had a very hypersensitive skin an irritant erythema developed. As this was not the result of any misconduct on either the part of the defendant-hospital or the attending physician, the plaintiff's attorney discontinued the action, thereby terminating the proceeding in the doctor's favor without trial.

## LONDON LETTER

Forceps in Abdomen: The danger to which a surgeon is constantly exposed during the prosecution of his art, is well exemplified by a case recently decided in the Law Courts. Eight years ago a woman was operated upon by the defendant in the case, a hysterectomy being done. Two years ago, that is six years after the first operation, a second operation was performed by another surgeon in a different country for disease of the gall bladder. Recently, as the patient seemed to be making no progress, an x-ray examination took place which revealed the presence of a pair of pressure forceps within the abdomen. An action for damages was brought against the first surgeon and after a very full and careful hearing was decided in the surgeon's favor on the grounds that there was no evidence that he was the surgeon who left the forceps behind. The case naturally excited much interest, but as it was decided on a question of fact, the much more important question of the responsibility of the surgeon in cases of this nature, was not decided. We are still without a definite legal ruling in this country on the question whether, if a swab or other foreign body is left in the abdomen after an operation, the surgeon is solely responsible. The matter was settled in 1929 in South Africa and a ruling was given that it is a reasonable and proper practice to rely upon the operating theatre sister to check swabs and instruments, but that apparently is not the law in England. How then do we stand? It is, I suppose, almost the universal custom in this country to ask the Theatre Sister, before the abdomen is closed, if the count of swabs and instruments is correct, and upon her assurance to close the abdomen. At the same time it is the custom to consider the surgeon responsible for the actions of his assistants and some very pretty legal arguments may well arise. Is the Sister a "servant" of the surgeon even though he does not appoint her nor pay her wages? Is the surgeon himself a principal or merely the agent of the family physician who calls him in to perform the operation? Or again, suppose the patient loses his life or suffers a long and expensive convalescence as the result of a fault in the sterilization of the swabs or the catgut -is the surgeon responsible for using these unsuitable materials, which have been prepared in another department over which he has no control, or even, in the case of the catgut, in another country? I feel that I would enjoy these arguments more whole-heartedly if I

were the lawyer rather than the defending surgeon. But, however we look at it, there is no doubt that if the surgeon has to check the swabs and instruments before he closes the abdomen, the patient must suffer, for the task involves not merely the counting and checking but a re-sterilization of the surgeon's hands, a change of gloves and gown before he can complete the operation, and thus at least fifteen minutes is added to the time of the operation.

Graduate Education: At last, after nearly five years' deliberation, the Ministry of Health has issued the report of the Committee appointed "to draw up a practicable scheme of post-graduate medical education centered in London." Those of us who are interested in this subject had begun to despair of anything being done. We had long realized that London with all its wealth and material lagged far behind many cities on the Continent of Europe in the efficient handling of their material for the benefit of qualified medical men. It had been proved that graduates and under-graduates cannot be taught together. The graduate does not require the instruction which suffices to get the undergraduate through his examinations, and the staffs of the teaching schools cannot find time to perform both duties. Some fine work has been done since the war by the Fellowship of Medicine which, by affiliating some fifty general and special hospitals in London, provides a comprehensive course of instruction, but it has always been felt that no real progress could be made until there was a centrally situated Hospital in London devoted to post-graduate teaching. Such an ideal has been attained at last and a large infirmary has been acquired under the authority of the London County Council and will in due time house a great Postgraduate Hospital. I shall have more to tell you as the scheme develops, and in the meantime it is enough to say that the whole profession welcomes the Government's decision.

It was the great Dr. Johnson who said, "Sir, when a man is tired of London, he is tired of life." I am not tired of life but Spring and Easter were too much for my stoical endurance, and I fled, for too short a space, far into the West Country, to Cornwall, King Arthur's country, the land of primroses, of golden sands and granite rocks. A heavenly week of glorious sunshine, and keen gales which blew the London smoke away. And now back again. All is very well.

H. W. Carson, F.R.C.S.

## NEWS NOTES

## THE ANNUAL MEETING

The annual meeting of the Medical Society of the State of New York was held from Monday to Wednesday. June 2 to 4, 1930, in the Seneca Hotel, Rochester, according to the programs and announcements contained in this Journal in the issues of April 15, May 1 and May 15. In addition the special Committee on Periodic Health Examinations arranged a popular meeting for Wednesday evening, after the close of the annual meeting, and the staffs of the several hospitals of Rochester gave clinics on Thursday.

There were also meetings of organizations allied to the State Medical Society, including the annual meeting of the Women's Medical Society of the State of New York. The Public Health Laboratory Association held a meeting on Mon-The District Health officers of the New York State Department of Health also held a conference under the leadership of Dr. Thomas P. Parran, State Commissioner of Health.

The registration exceeded 850, while over 150 ladies accompanied their medical husbands, and 100 persons were present in charge of the technical exhibits. Altogether over 1,200 persons came to Rochester on account of the annual meeting. The hotel accommodations were ample and the service was unusually satisfactory. The weather was auspicious and according to all outward signs every visitor had an unusually good time.

The perfection of the local arrangements assured the satisfaction of the visitors. The Physicians of Rochester added to the reputation of the City for friendliness, and the Chamber of Commerce showed its concern for the comfort and convenience of the visitors by maintaining an information booth near the registration table of the Society.

The Seneca Hotel was well adapted for the annual meeting, for its spacious lobby furnished with easy chairs afforded ample space for the guests during their moments of leisure; its two mezzanine floors gave abundant room for the technical exhibits; and the large banquet hall and smaller rooms within easy access provided abun-

dant meeting space. The concentration of all the features of the annual meeting in a large hotel was an insurance against almost every emergency that might arise. The smaller requirements of chairs, messenger service, and committee rooms were always instantly met, while information was available on every public subject. The managers of the Seneca Hotel made a substantial contribution to the reputation of Rochester for a friendly interest in its guests.

The Medical Society of the County of Monroe was the official host of the Medical Society of the State of New York. The details of the local plans for the annual meeting were in charge of a Committee on Arrangements composed of the following physicians living in Rochester:

Walter A. Calihan, Chairman; Austin G. Morris, Floyd S. Winslow, Benjamin J. Slater, Benjamin R. White, Leo F. Simpson, Charles Lenhart (Spencerport), Sol. J. Appelbaum, and John Aikman.

The Sub-Committees were as follows:

Banquet: Floyd S. Winslow, Chairman, and Benjamin J. Slater.

Public Meeting Periodic Health Examination: William A. Sawyer, Chairman, Austin G. Morris and Walter A. Calihan.

Meeting Places and General Arrangements: Walter A. Calihan, Leo F. Simpson, and Benjamin R. White.

Hotels: Sol. J. Applebaum; Publicity: Benjamin J. Slater, Chairman, and John Aikman.

The newspapers of Rochester were cooperative and public spirited, and their editors made every effort to report the proceedings truthfully and with a due consideration of the viewpoint of the medical profession. The reporters were quick to grasp information and diplomatic in their approach to the speakers and medical leaders. The present attitude of the Press of Rochester recalls the following paragraph from page 643 of the issue of May 1924, on the occasion of the annual meeting of that year held in Rochester:

"The daily newspapers of Rochester were most cordial in their relation to the meetings. editor of this Journal made it a special point to call at the newspaper offices and to offer news facilities to the press. The reporters were most kind and considerate, and showed a broad grasp of what constitutes up-to-date medical news. The physicians, too, were most kind in their cooperation with the reporters, and altogether a new standard was set in the relation of physicians to the newspapers."

The interest and enthusiasm of the physicians of Rochester in the annual meeting was demonstrated by their zeal in preparing a minstrel show given entirely by local physicians. Writing the libretto called for extensive effort and study, while rehearsals of the parts required hours of time which were contributed with all the enthusiasm of golfers.

The impressions of the doctors regarding the annual meeting are necessarily colored by the

experiences of then wives were royally entertained by a committee of the wives of the Doctors of Rochester under the chairmanship of Mrs Austin G Morris On Tuesday the ladies were taken on a ride to the points of interest, including Highland Park on the southern edge of the city where the izalias and rhododendrons were in bloom in a mirrelous profusion of brilliant colors. The guests were

given a noon luncheon at the Oak Hill Country Club followed by bridge, and bridge was provided for the afternoon

On Wednesday a block of 150 seats was as signed to the visiting ladies for the play. The

Coquette' in the Lyceum Theitre

The bringuet and ministral show on Tuesday evening were for the benefit of the ladies as well as the doctors

### PRESIDENT'S DINNER

Dr James N Vender Veci President of the Medical Society of the State of New York revived an old custom when he gave a dinner to his brother officers and the prist presidents of the Society in the Hotel Seneca, Rochester, on June first, on the evening before the opening of the Annual Meeting There were present twenty two officers and twelve past presidents

After the dinner Dr Vander Veer presented a brass hammer to each guest, and asked him to use it either in knocking the present administration or in hammering and molding the new one into a shape so that it will exactly fit the changing needs of these modern days

of progress and advancement

Dr Wendell C Phillips, President of the State Society in the year 1912, and of the American Medical Association in 1926, told of the annual dinners given by the Presidents of the State Society up to a very few years before he became President Those dinners constituted almost the only general assembly of the medical leaders during the year, and Dr Phillips drew a contrast between those days—recent in actual time, but fai away in achievement and progress,—and the present year when the President attends at least a hundred conferences, many of them of a public nature

Dr Phillips described the former methods of conducting the scientific sessions when authors came to the meeting with their articles in their pockets and rose in their places asking for recognition and permission to read their papers at the pleasure of the presiding officer. Dr Phillips made it the work of his presidential year to organize the scientific sections and to list the papers in a published

program

Dr James F Rooney recalled Dr Albert Vander Veer, father of the president, who was a pioneer leader in giving modern laboratory instruction to medical students, and in developing the State Medical Society along modern lines

Dr William H Ross President-elect of the State Society, gave his impressions of the activities of the State Society during the past year and told how he would wield his ham mer constructively in forging new methods to meet new conditions of medical practice. He

"My experience as President elect has brought me from the intellectual heights where we live apart from our fellows to the level plain of practical experience where we spend our daily lives. I have met this year and talked with forty seven groups of physicians, as well as many official and voluntary organizations and heads of departments of the State government Including committee meetings. I have taken some part in one hun dred and two meetings in organized medicine be tween June 1, 1929 and June 1, 1930 The result of all this is an impression that the practice of medicine is changing in response to public needs and public demands

"My year of observation as President elect has oriented me regarding the problems of the profession, and what we ought to do about them

"The activities of the State Medical Society are carried on by fifteen committees, some of which deal with special matters such as legislation, and medical research while others affect family doctors immediately and inti-The Committee on Public Health and Medical Education seeks to reinstate the family doctor in the high opinion of the people by making him a better physician. The last committee to be formed is that on Public Relations which seeks to interpret the practice of medicine to other organizations which pro-The Committee considers the mote health social trend of the times in an effort to discover why people go to cultists, Indian doc tors, and clinics rather than to their family doctors The Committee is advising departments of health and endowed health agencies how they may fit their methods into the practice of medicine by family doctors, and at the same time it is advising practicing physicians how they may meet the opportunities in new fields of practice created by the voluntary orgamizations The Committee is still faced with the task of inspiring every invidual doctor to assume a leadership in solving the medical problems of his community

### HOUSE OF DELEGATES

The House of Delegates of the Medical Society of the State of New York, composed of the officers of the Society, the Past-Presidents, and 150 delegates from the County Medical Societies, met on the afternoon of Monday, June 2, 1930, at two o'clock, with practically a full representation present. The speaker, Dr. John A. Card, of Poughkeepsie, presided, and the records were kept by the Secretary of the State Society, Dr. Daniel S. Dougherty, and the Assistant Secretary, Dr. Peter Irving, assisted by two stenographers. Three sessions were held on the afternoon and evening of Monday, and the morning of Tuesday. The members dined together on Monday evening in order to facilitate the proceedings.

Business was transacted with unusual smoothness and dispatch, in contrast with the controversies which formerly arose when the delegates came together uninformed regarding the problems to be discussed. In the year 1927, the Society instituted the custom of printing the annual reports of the officers and committeemen in the Journal in advance of the annual meeting; and this year the officers took the further steps of publishing the names of the members of the Reference Committees two weeks before the meeting. These reference committees met on Monday morning so that they had abundant time to investigate all the questions which were submitted to them.

Another factor which promoted the transaction of business in a wise manner was that frequent meetings of the officers and committeemen had been held during the year and their proceedings had been published in current numbers of the Journal. The Delegates therefore came to the Annual Meeting informed of the activities of the Society, and were prepared to vote intelligently on nearly every question. It was a striking fact that every controversial question and every suggestion for extending the field of the activities of the State Society had been under discussion

during the year, and that some committee was prepared to give a definite opinion regarding the subject. The discussion revealed an unexpected breadth of the investigations, and a comprehensiveness of decision on the part of the officers and committeemen. The proceedings were convincing evidence of the great extent which the intelligent evolution of State Society activities have undergone during the last decade.

All the reports of the activities of the year were commended, and all suggestions for their further development were approved. Yet most of the suggestions for undertaking new activities were not adopted, so far as their immediate

establishment was concerned.

The suggestion that aroused the most discussion was that of the President that an extensive bureau for preparing press notices, radio broadcasting, and lectures be established. The fact was brought out that the Executive Committee of the Council had considered the subject at length and its members felt that further evidence should be collected and plans evolved before the Society enters the extensive field of the press, the radio, and the lecture platform. The House agreed with this point of view, but it also authorized the appointment of a special committee on popular education in cancer prevention to act as a sub-committee under the Committee on Medical Education.

The House also authorized the appointment of a special committee on the subject of the Wo-

man's Auxiliary.

The House approved the President's suggestion that the Society promote the collection of historical records and mementos of a medical nature to be deposited in the State Museum.

The detailed minutes of the proceedings of the House of Delegates, being dependent on the transcription of the notes of the official stenographer, will be published in the Journal in as early an issue as possible,—probably in that of July first.

## THE SCIENTIFIC SESSIONS

The Scientific sessions at the Annual Meeting of the Medical Society of the State of New York were of unusual interest and were well attended. The general sessions held on Tuesday and Wed-

nesday afternoons were of special interest to all physicians. The papers presented at all the sessions will be published during the year in our *Journal*.

### THE BANQUET, THE ANNIVERSARY MEETING, AND THE ENTERTAINMENT

The evening of Tuesday, June 3, was given over to three events:

The annual banquet.

The anniversary meeting

3. A minstrel entertainment The banquet was the social event of the annual meeting and was held in the Hotel Seneca at seven o'clock in the ballroom, which was filled to its capacity with doctors and their wives. In place of the usual after-dinner speaking, a brief session of the Anniversary meeting was held in accordance with the Charter of the Society. The program of this meeting consisted of the inaugural address by Dr. W. H. Ross, as he assumed the presidency of the Society. This address is printed as the first article of this Journal, page

Following the Anniversary meeting, an entertainment and minstrel show was given by a troupe composed almost entirely of physicians practicing medicine in Rochester. These doctors had devised the plots, written the songs, and adapted the minstrel jokes to some of the leaders

in the State Medical Society.

The introductory number on the program was a brief one-act farce entitled "The Miracle Man" or "Quick, Ben, the Needle," based on an actual experience in which a man who had dropped apparently dead had been restored to life by the injection of adrenalin into his heart by Dr. Benjamin J. Slater of Rochester. The scene of the Act was laid in the Monroe County Morgue and the actors were as follows:

Dr. B. J. Slater	
Interne	Dr. L. A. Kohn
Pathologist	Dr. F. S. Wińslow
Undertaker	
Corpse	Dr, G. M. Gelser
The principal feature of	the entertainment was

a minstrel show, given according to the following program: DARM T

	- AKI I.	
1. (	Opening Chorus	Minstrels
	a. Heigh Ho	
	b. Way Down South	
2. 5	Solo-Lindy Mrs. E.	Γ. Wentworth
3. 1	Parody—Memories	Minstrels
1 1	Dames Destinant to the S	D

- 4. Dance—Beating Against the Beat
  Dr. E. T. Wentworth 5. Song-Tweet, Tweet ...... Minstrels
- 6. Solo-Tip Toe Through the Tulips
- Dr. M. V. Rapp 7. Chorus—Stein Song ......Miustrels
  PART II
- 8. Chorus—Happy Days .........Minstrels
- 9. "Hula Dance" .........Dr. J. B. Loder

- 10. Parody-Painting the Clouds With Sunshine .......... Minstrels
- 11. Solo-Indian Love Lyrics. Dr. Cecil Hert

12. Solo-Can't Yo Hear Me callin',

Caroline? . . . . . Dr. P. W. Beaven

13. Duet-Negro Spiritual

Mrs. John R. Booth and Mrs. E. T. Wentworth

14. Closing Chorus-In Bohemia Hall Minstrels

The numbers were happily rendered, some of the more notable ones being a clog dance by Dr. and Mrs. E. T. Wentworth, a song in falsetto voice by Dr. Cecil Hert, in the costume of a chorus girl, and a serious rendering of negro spirituals by Mrs. E. T. Wentworth and Mrs. John R. Booth.

Those taking part in the minstrel show were

as follows:

Interlocutor, Dr. B. J. Slater End Men: Drs. F. J. Garlick, A. L. Parlow,

C. P. Thomas and E. T. Wentworth.

Members of the Chorus: Drs. E. S. Amsler, D. H. Atwater, P. W. Beaven, W. E. Bowen, N. Brown, F. J. Colgan, W. I. Dean, J. B. Deuel, J. J. Finegan, C. B. F. Gibbs, J. H. Green, E. I. Guller, J. L. Hazen, B. Hert, C. Hert, J. J. Lloyd, J. B. Loder, H. R. Leve, W. A. MacVay, N. G. Corbed, E. Benedik, P. R. Leve, W. A. MacVay, N. G. Orchard, E. Parnell, L. Pulsifer, M. V. Rapp, M. J. Rhees, F. L. Slater, J. W. Thomson, W. R. J. Wallace.

At the Piano: Dr. I, Hurwitz (in person).

Musical Director: David Harvard.

Costumes: Henry Herbst.

Leer-ics, written by: Mrs. S. S. Bullen, Mrs. F. S. Winslow, Dr. L. W. Jones, and Dr. C. P.

The character of the "Leer-ics" is shown by

the following sample:
"The State Society, as every one can see,

Is always filling your hearts with sunshine. With Orry Wightman, boss, Heyd, Overton and Ross

The Journal fills all your hearts with sunshine. Science and news, snappy reviews, done in an elegant style,

Editor's views interest infuse or make you

So, if you're feeling glum just have the Journal come-

That it may fill all your hearts with sunshine. Those who composed and enacted the numbers on the program of the entertainment deserve the congratulations and appreciation of the members of the Medical Society of the State of New York.

## ANNUAL MEETING

THE TECHNICAL EXHIBITS

The technical exhibits are an important feature of the annual meeting of the Medical Society of the State of New York, as they are of the annual meetings of other States and of the American Medical Association. The exhibits this year were unusually well arranged and accessible to the physicians. Six pages of the formal Program were devoted to a description of the wares of the forty-five exhibitors, whose exhibits showed a wide range of articles from surgical instruments. to drugs and foods. Nearly all the exhibitors were patrons of the advertising department of the Journal, and were old friends and supporters of the State Society. Good will and fellowship were promoted by a dinner given in the Hotel Seneca on Monday evening by the State Society to the exhibitors, at which eighty-one guests were present. The attitude of the State Society was explained by Dr. O. S. Wightman, Editor-in-('hief of the Journal, who presided. The speakers giving short talks were: Dr. Wendell Phillips, past-President of the A. M. A. and of the Medical Society of the State of New York; Dr. James N. Vander Veer, outgoing President of the Medical Society of the State of New York; Dr. W. H. Ross, incoming President; Dr. Frank Overton, Executive Editor of the Journal, and Dr. Walter A. Calihan, Chairman of the local Committee on Arrangements.

Responses were made by Mr. W. P. Schmid, Manager of the Eastern District Office of the Cameron Surgical Specialty Company of Chicago, and by Mr. J. B. Martell representing the Olajen

Company of New York City.

The guests joined enthusiastically in chorus singing led by Mr. J. Henry Slater, a well-known local entertainer of Rochester.

The Department of Labor of the State of New York also conducted an exhibit dealing in a historical way with accident prevention and advances made in industrial and personal hygiene.

## CLINIC DAY

Thursday, June 5, the day after the close of the Annual Meeting, was *Clinic Day*, conducted under the auspices of the Medical Society of Munroe County. The response of the members of the Medical Society of the State of New York

### 8:30 A.M. to 10:30 A.M.

## St. Mary's Hospital

- 1. Spinal Anesthesia Clinic.
- 2. Pediatric Clinic.

### Rochester General Hospital

The practical management of severe Graves' disease.

### Highland Hospital

- 1. Demonstration in Diabetic Service.
- 2. Case Presentations. Addison's Disease. Purpura Hemorrhagia.

### Genesee Hospital

- 1. Hypoglycemia. Case report. Dr. McGarvey.
- 2. Fragillitus Ossium. Case. Dr. Glasser.
- 3. Acute Mononucleosis. Case. Dr. Segal.
- 4. Supernumerary Ureter. Case. Dr. Paine.
- Bone Cyst Inferior Maxilla. Two cases. Dr. Sumner.
- 6. Sodium Amytal Intravenous Use. Dr. Desslock.
- Embolism of Abdominal Aorta. Case report. Dr. Jewett.
- 8. Three cases of Ruptured Gall Bladder. Dr. Mitchell.

## Park Avenue Hospital

Cancer Experience. A hospital study.

Rochester State Hospital

Childhood Tuberculosis.

was gratifying, the registered attendance being 104, exclusive of physicians living in Rochester and the members of the staffs of the hospitals. The program of the day as carried out by the

# several hospitals of Rochester was as follows: 11 A.M.

The University of Rochester, School of Medicine Strong Memorial Hospital

- 11:00-11:20—A Hormone of the Corpus Luteum. Dr. George Corner, Prof. Anatomy.
- 11:20-11:40—The Toxic Factor in Peanut (Aspiration)

  Bronchitis. Dr. S. W. Clausen, Prof.

  Pediatrics.
- 11:40-12:00—The Use of the x-ray in Obstetrical Diagnosis. Dr. Karl Wilson, Prof. Obstetrics.
- 12:00- 1:00—Clinical Pathological Conference. Dr. George Whipple, Prof. Pathology.
- 1:00- 2:00-Lunch. Strong Memorial Hospital.
- 2:00- 2:30—A Comparison of the Serological Tests for Syphilis. Dr. Stanhope Bayne-Jones, Prof. Bacteriology.
- 2:30- 3:00-Progressive Muscular Dystrophy. Dr. W. S. McCann, Prof. Medicine.
- 3:00- 3:20—Studies on the Activity of the Sympathetic Nervous System. Dr. J. J. Morton, Prof. Surgery, and Dr. W. J. Merle Scott, Assoc. Prof. Surgery.
- 3:20- 3:40—The Life History of the Yellow Fever Mosquito; Motion Picture. Dr. S. Bayne-Jones, Prof. Bacteriology.

### CONFERENCE ON PERIODIC HEALTH EXAMINATIONS

The Committee on Periodic Health Examina tions of the Medical Society of the State of New York, held an open meeting and banquet, in connection with the Medical Society of the County of Monroe and the Rochester Chamber of Commerce on the evening of June 4th, after the Convention of the Medical Society of the State of New York had formally closed. About 250 persons were present.

The purpose of this meeting was to bring into conference under the auspices of organized medicine, some of the most vigorous, pervading and helpful of the organized social forces of the State, to the end that new powers, from better understanding and better organization, may be exerted toward the realization of one of the public health aims of the State Society, i. e., "a health examina-

tion for every citizen of the State.'

The Committee on Periodic Health Examinations wished to make a presentation of a typical cooperation conference as its last contribution of the year to the work of the Medical Society of the Sate of New York, and to add the results of this conference to the results of its labors of the preceeding twelve months.

The forces represented were as follows:-

#### FEDERAL

The Chief Executive, Herbert Hoover, whose leadership is exerted in many national, humanitarian affairs, particularly through the White House Conference on Child Health which includes the Health Examination program, was interested in our large emphasis on preschool health examinations through "The Summer Round Up," and wrote as follows;

"I am indeed gratified that an important part of the annual convention of the Medical Society of the State of New York has been given to consideration of problems of childhood. To make the childhood of the nation well and strong in mind and body is to take the first and indispensable step in insuring the future safety and well-being of the nation."

The Defartment of the Interior: -This Federal Department, through its Bureau of Education. reaches about two million or more children in the State, a large proportion of its population. Through the leadership of its Secretary, Ray Lyman Wilbur, who is a physician, the health of the Nation has benefited in various ways. He wrote the following letter:-

"The application of modern science to the care of the sick and the protection of the well, demands for its best results, the periodical health examination as the base from which all proper work should start. The greatest value of the family doctor is his knowledge of the bodies,

personalities and reactions of his patients. carries with him on each visit carefully sifted information gathered through past experiences. We now have the opportunity, with regular health examinations, to have available for the benefit of the patient and the guidance of the physician, a written record of exact conditions as they existed at a given date. With our gradual conquest of many infections, there is an increasing importance in following accurately the changes in the vital organs of the body due to disease, strain and advancing age. We are fortunately in the possession of many methods by which we can check or delay the processes going on in the human body. The skilled physician can become both the guardian and the guide of the patient if he can have the advantages of carefully built-up records giving the body conditions and the health experiences of each individual.

"I am heartily in sympathy with every effort that is being made by the Medical Society of the State of New York to advance the periodical health examination in that State."

The two outstanding Federal health officers at Washington, Surgeon General of the Army, Merritte W. Ireland, and the Surgeon General of the Public Health Service, Hugh S. Cumming, presented their felicitations in letters, from which the following is quoted from the letter of General Cumming:-

"It is gratifying to note that the Medical Society of the State of New York is conducting such a campaign. It is highly desirable for the organized medical profession to assume the place of leadership in endeavoring in every possible way to bring before the general public the importance of periodic health examinations. This is a matter of public health significance which should receive the support of the medical profession as well as the various public health authorities.

"In conducting such a campaign to stress the necessity for periodic health examinations the Medical Society of the State of New York is rendering an important service to the cause of public health."

Out of the many bureaus at Washington, interested in this occasion, the following excerpt from Grace Abbitt, the Chief of the Children's Bureau of the United States Department of Labor, is given:-

"The logical person to give this supervision is in the great majority of cases, the family physician. We have found that parents needed to be convinced of the importance of having the doctor examine the well child at regular intervals and advising as to the establishment of those habits all important for health, immunization

against disease, and corrections of defects. Some parents still think that the physician is to be called in only when the child becomes ill."

"In sending my best wishes to your committee for its success, let me assure you that the Children's Bureau is doing all in its power to bring home to parents the fact that intelligent use of the services the doctor is prepared to give is necessary for the optimum health of the child."

## STATE

The State was represented by its chief medical officer, Commissioner Thomas Parran, who graced the occasion by his presence, and who spoke of he service of the State Department of Health to the people and the medical profession, giving concrete assurance of powerful cooperation in the Health Examination movement.

A letter was received from State Commissioner of Education, Frank P. Graves.

This meeting and its subject naturally attracted some attention in the medical profession outside of New York State. Dr. Lewellys F. Barker, had accepted an invitation to address the meeting but was unfortunately called abroad-

Dr. George W. Crile, however, was able to be present, and he gave a stirring address showing the progress of medicine up-to-date, and picturing the future of medicine as it seemed to him that the process of evolution discernable today might produce in the future. His address gives the strongest support to the Health Examination movement, from the standpoint of practical medicine, science, and sound philosophy.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

The meeting was predominately an event in organized medicine as attested by the prominent part taken in it by the officers of the State Society. The retiring President, Dr. James M. Vander Veer, introduced the Acting Mayor of the City of Rochester, Honorable Isaac Adler. The Committee on Periodic Health Examinations was appointed by Dr. Vander Veer and the work of the year was conducted under his auspices.

Dr. Charles Gordon Heyd, Treasurer of the Society, spoke from the standpoint of historic medicine, and surgery and introduced Dr. Crile.

Dr. James E. Sadlier, Chairman of the Committee on Public Relations, gave a brief address, which presented clearly the necessity of organized medicine not only recognizing outside organization, with an alignment of purpose and a conjunction of effort. He sketched one of his most recent and important conferences in this field, and recognize the importance of the current occasion, and pledged further cooperation.

Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education, whose Committee is in parental relation to the Committee on Periodic Health Examination pre-

sented a clear-cut picture of the work of his Committee in its relation to the health examination, and outlined a forward-looking program of cooperation.

The meeting was closed by the new President of the Medical Society of the State of New York, Dr. William H. Ross, who emphasized the necessity of organized medicine avoiding the perils of isolation, and of taking its own part of leadership in the world of health affairs.

Emphasizing the fact that the State Society is composed of County Medical Societies, from which it derives its whole life and authority, the meeting was indebted primarily to the far-seeing plans and effective constructive ability of Dr. Walter Calihan, the Chairman of the State Committee on Local Arrangements. Dr. Calihan was presented, made a brief address, and read excerpts of his own selection from the messages received by the Chairman.

## ORGANIZED BUSINESS

In its health education project which affects the whole body politic, the Committee seeks to deal with large masses of human beings, already organized, and subject to approach en masse. The human material throughout the State is organized in many ways, and is approachable through many open highways. One of these large forms of organization is the Chamber of Commerce. It was most fitting that this meeting was held at the Rocheser Chamber of Commerce, and that the man who attended to its intimate arrangements was the Chairman of the Health Committee of the Chamber of Commerce, Dr. William A. Sawyer. Dr. Sawyer introduced the Chairman. Dr. Sawyer also represents an enormous field of effort in potential cooperation in industry, as the Chief of the Medical Health Service of the Eastman Kodak Company.

The Chamber of Commerce of the United States during the last few years, has been working with the American Public Health Association, and was represented by a long and interesting message from the Chairman of the Board of Directors, Julius H. Barnes, who organized the intercity Health Contest of the Chamber of Commerce of the United States of America.

The largest representation of human forces already organized and in operation in the health field was presented by four women's organizations. The General Federation of Women's Clubs reaches directly and indirectly through its membership, one-third of the population of the State. It was represented by Miss Harriet W. Mayer, who is Chairman of its Health Committee. She presented an address setting forth a health program of the General Federation of Women's Clubs already in operation, in cooperation with other health organizations.

The National Congress of Parents and

Teachers, which has for years been conducting an increasing campaign for health examinations for preschool children, reported on its work through the Chairman of its Health Committee, Mrs R R Vail This organization is already in cooperation with the Association and through the Chairman on Public Relations their former projects have been reported in the State Journal

The presence of Dr Marion Craig Potter, Health Chairman of the Business and Professional Women's Clubs of New York State, and Dr Daisy M O Robinson, President of the Wo

men's Medical Association, completed the schedule

Thus, there were assembled at this meeting, some of the representative forces of the Nation, State and City, organized business, organized wo men's clubs, all under the auspices of organized medicine, all focused upon a program of medical service for the citizens of the State, through Health Examinations

C WARD CRAMPTON, M D, Chairman, Committee on Periodic Health Examinations

### WOMEN'S MEDICAL SOCIETY

The twenty-fourth annual session of the Women's Medical Society of New York State, Inc, convened in the Seneca Hotel, Rochester. June 2nd In the morning the machinery of business was set in motion, officers for the ensuing year were elected and reports of execu tives and committee heads were given inspirational part of the program was the message from the President, Daisy M O Robinson. M.D., Assistant Surgeon General of the United States Dr Robinson with her broad interests, wide vision, and keenness of mind has guided the society through a most successful year

The afternoon program was launched by greetings from the New York State Medical Society brought by the President Dr J N Van derVeer, and President-Elect, Dr Wm H Ross Dr VanderVeer, with his wide experience and sympathetic foresight, gave an address which contained sound advice and prophecies for the future His subject was aptly phrased "A Hand

muden to Public Health Measures"

Dr Ross, president-elect, gave a most timely address picturing the past, present and future of medicine He noted the changes in medicine with the succeeding years and said, "The transition is not entirely painless. Preventive medicine is not a new thing, but part of an evolutionary process "

The program continued with scientific papers by members of the society In the realm of gynecology and obstetrics were two papers The Diagnosis of Various Forms of Leukor rhea—Emily Dunning Barringer, M D, of New York City 2 Some Unusual Obstetrical Experiences-Esther Parker, MD, of Ithaca

The subject of Diabetes in the elderly indi vidual was ably discussed by Agnes Brown M D, of Rochester

In line with public health promotion was a report on a survey made and Pierce, M.D., Syracuse, on "

School Child About to Enter

As a climax to the public health discussion there was a brief and stimulating address by Thomas Parran, Jr., M.D., Commissioner of Health, State Department, Albany Dr Parran stated his convictions that women physicians are needed in many of the administration offices of the Department of Health

Professional women are sometimes stigmatized as lacking the spirit of play, but the evening program of the Women's Medical Society contra dicted such an accusation A friendly banquet at 6 30 P M, in which frilled and frivolous femininity prevailed, was held in the Blue Room Twelve women students of the Seneca Hotel of the Medical College of the University of Rochester were dinner guests Following the banquet dramatic potentialities unfolded them selves in the "make up" and extemporaneous interpretation of the medical high-lights of history This all refers to the pageant, "The Highway of Health," written for the occasion by Mary Newman Sloane, MD, of Buffalo, and presented by Dr Sloane and a cast of the fol lowing members of the Women's Society

Mary Newman Sloane, M D Marion S Morse, M D Esther Parker, M D Soothsayer Father Time Primitive Man Moses Alta Sager Greene, M D Louise Beamis Hood, M D Sophy Page Carlucci M D Kathryn Bayliss MacInnes, M D Hippocrates Galen Ambroise Pare Helena Isabelle Borden M D American Indian Katherine F Carnivale M D Ruth Moore M D Louise M Hurrell M D 'Valsh, M D De Vinci Paracelsus Buck M D Bull Queen Victoria Luzabem Merle M D Daisy M O Robinson, M D John Stoan Property Man and Artist

The evolution of Medical Progress through the ages was depicted by impersonation of a line ... amon of the nast

ery, and then Moses, the patriarch, with his laws of health and hygiene. Climbing up through the centuries we saw Hippocrates, Galen, Helena, the American Indian, De Vinci, Vesalius, Paracelsus, Ambroise Paré, St. Catherine, Sanctorius, and Harvey. With the reign of Queen Victoria came the introduction of chloroform a la reine, and its introducer, Dr. Simpson Jenner, Lister and other names were beacons in the great parade of the decades. As the years approached our century and our time, we began to look into the future and hoped for the fulfillment of perfeet health. This climax was represented by a posed figure,—Radiant Health,—embodying the ideal of healthy motherhood, the highest product of the race.

The officers elected for 1929-1930 were as follows:

President—Louise Beamis Hood, M.D. Vice-Presidents—Anna P. Walsh, M.D., Mary C. Conant, M.D., Isabel Meader, M.D. Treasurer—Mary J. Kazmierczak, M.D. Secretary—Sophy Page Carlucci, M.D.

#### Councillors-

1st District Branch, Marie L. Chard, M.D.
2nd District Branch, Mary E. Potter, M.D.
3rd District Branch, Emily A. Pratt, M.D.
4th District Branch, Annette Barber, M.D.
5th District Branch, Ruth D. Moore, M.D.
6th District Branch, Edith F. Wheeler, M.D.
7th District Branch, M. Louise Hurrell, M.D.
8th District Branch, Clara March, M.D.

#### Committee Chairmen—

Scientific Program, Marion S. Morse, M.D. Legislative, Florence Sherman, M.D. Medical Education, Mary T. Greene, M.D. Public Health, Daisy M. O. Robinson, M.D. Public Relations, Mary N. Sloane, M.D. Membership, Marie I. Chard, M.D. Resolutions, Alta Sager Greene, M.D.

MARION S. MORSE,

Secretary, Program Committee.

#### LABORATORY MANAGERS' CONFERENCE

A conference of the Managers and Directors of approved Public Health Laboratories of New York State was held in the Hotel Seneca, Rochester, N. Y., on the morning of Monday, June 2, 1930, with Dr. C. F. M'Carthy, of Auburn, presiding. The following program was carried out:

Welcome. Dr. Leo F. Schiff, Clinton County Laboratory, Plattsburg, President, New York State Association of Public Health Laboratories.

Remarks. Dr. Augustus B. Wadsworth, Albany, Director, Division of Laboratories and Research, New York State Department of Health.

The County Laboratory as an Aid to the Hospital: Dr. V. A. Moore, Ithaca, Superintendent, Ithaca Memorial Hospital, and Chairman, Board of Managers, Tompkins County Laboratory. Discussion opened by Dr. Homer J. Knicker-

bocker, Geneva, member of Staff, Geneva City Hospital.

The Laboratory as a Part of the County Health Unit: Dr. Arthur T. Davis, Riverhead, Commissioner of Health, Suffolk County. Discussion opened by Dr. Daniel R. Reilly, Cortland, Commissioner of Health, Cortland County.

Selection of the Director of a County Laboratory: Dr. Cornelius F. M'Carthy, Auburn, Secretary, Board of Managers, Cayuga County Laboratory. Discussion opened by Dr. Henry R. Sutton, Ithaca, member Board of Managers, Tompkins County Laboratory.

Round-Table Discussion of Laboratory Matters: Conducted by Dr. Howard P. Carpenter, Poughkeepsie, Director, Poughkeepsie City Laboratory, and supported by practically every member present.

#### AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY

The American Academy of Ophthalmology and Otolaryngology will hold its thirty-fifth Annual Meeting on October 27-31, 1930, in the Hotel Sherman, Chicago, Illinois. The folder

of the preliminary announcement contains the following information of special interest to physicians of New York State:

"The Academy has in contemplation, the crea-

tion of a new section for teachers-undergraduate and graduate. A casual thought seems to offer wonderful opportunities for this section. Dr. S. J. Kopetzky of New York City and Dr. A. J. Bedell of Albany, N. Y, under the direction of Dr. Harry S. Gradle, Secretary for In- eral committee.

struction, have the preliminary plans in hand, Comments and suggestions will be appreciated. and should be sent to the Executive Secretary, Dr. W. P. Wherry, 1500 Medical Arts Building. Omaha, Nebraska, or to any member of the gen-

#### MEDICAL VETERANS' DINNER

The annual meeting and dinner of the Medical Veterans of the World War will take place Sunday evening, June 22nd at 7:30 P.M. at the Italian Garden, Book-Cadillac Hotel, Detroit. The guest of honor will be Major General Merritte W. Ireland, Surgeon General, U. S. Army. The principal address will be given by Dr. Aristides Agramonte of the University of Havana, the only surviving

member of the Walter Reed Yellow Fever Commission. There will be a short musical program. Members are asked to bring ladies. Reservations should be made through Dr. Burt R. Shurly, 62 Adams Avenue West, Detroit. Plates \$2.50. Colonel John O. McReynolds, Aux. Res., the President of the Medical Veterans' Section of the Association of Military Surgeons, will preside.

#### WASHINGTON COUNTY

The Semi-Annual Meeting of the Medical Society of the County of Washington was held at the Mary McClellan Hospital at 4 P.M. on May 13, 1930.

Members present: Drs. LaGrange, Paris, Tillotson, Oatman, Vickers, Banker, McKenzie, Bailey, Stillman, Leonard, Sumner, Armstrong, Munson, Ring, Bennett. Orton, Fortuine and McArthur. Visitors: Russel Paris, Jr., D.D.S., and Dr. S. F. Randels.

The Treasurer's report showed a balance of

\$134.61 available for the society.

The Treasurer reported that Dr. Tenney's papers for retired membership had been completed and sent to the Secretary of the State Society.

The Secretary read a list of lecture courses sent to him by Dr. Farmer. After some discussion the Comitia Minora was empowered to select one of the general courses.

After some discussion Dr. Munson was made a committee to find out the cost and feasibility of chartering a boat on Lake George for the meeting of the Fourth District Branch, and report to the Comitia Minora.

Dr. Tillotson read his Vice-Presidential address, reporting an interesting case of Angina

Pectoris.

Dr. Baker reported a case of a temperature of 108° and recovery.

Dr. Leonard gave a résumé of the 1930 Medical Legislation, and was given a vote of thanks for his work as chairman of the legislative committee.

Adjourned to the Cambridge House for

After dinner Dr. S. F. Randels spoke on the Five-Point Program of the Albany Medical College.

Dr. Munson gave a brief talk on public health matters of the county.

Adjourned at 9:45 P.M.

S. J. BANKER, Secretary.

## THE DAILY PRESS

#### MEDICAL ECONOMICS

Medical economics, adapted from J. N. Ding in the New York Herald Tribune of April 23, 1930.

Much is being said and written about the economic status of the family physician and his loss of revenue resulting from his efficiency in eliminating the diseases which have made his services a necessity. Yet the fact remains that physicians are more prosperous than ever before. The people have money and their liberality in spending it is reflected in the prosperity of the doctors.

If a doctor is not financially independent, the defect lies with the doctor himself, rather than the people. Most doctors have financial acumen excelling that of the average business man; but a few physicians lack monetary assertiveness, and no amount of instruction will give it to them.

It is undoubtedly true that the older doctor will fail if he depends on malaria and typhoid fever to bring him a living wage. It is probably too much to expect of him that he will change his point of view and learn to do blood transfusions, and to prescribe diabetic diets expertly. But still he will find large returns if he will fit up his office with a modern equipment, and be social with his younger associates and adopt some of their up-to-date methods.

There are three elements in the success of a physician:

- 1. Scientific knowledge and skill.
- 2. An agreeable personality.
- 3. Business acumen.

Given the first two qualifications, a moderate degree of business ability will ensure the doctor with financial independence.

#### SOCIAL WORKERS

The Social Worker is the title of an editorial in the New York Times of June 10 which says:

"Through several stages an applied social science has emerged which seeks to adjust social relations rather than simply to give relief and make repairs. Those in this expert service are not 'charity workers,' nor yet 'reformers,' but for the most part trained persons working in sympathy with human beings whose relation to their environment they seek to improve 'as to common and not separate wants,' though the effort in the end comes down to the individual. So many unknown quantities enter into every human problem that social workers cannot speak with the certitude of the exact scientist. Yet such wisdom as the race has accumulated in dealing with human nature 'out of heart and out of kilter,' as

Stevenson would have said, is placed at the service of the public.

"The integration of society is the supreme funcion of social workers, but they find their basic service in conserving as experts the 'spirit and substance' of the family life. They have become as necessary to our ever-changing social and individual life as physicians, lawyers, preachers and teachers."

The physician has come to consider the social worker as essential as the public health nurse, for she deals with the economic conditions relating to sickness, just as the nurse deals with physiological and pathological states. A social worker is almost a necessity in every hospital, in order to follow up the cases after their discharge from direct treatment.

#### RADIO TALKS

Radio talks are discussed editorially in the New York Times of June 1, as follows

"Almost every one who has listened over the radio will agree that ten minutes is long enough for most speeches. This is one of the rules laid down by Mr Sherman P Lawton of the Uni versity of Michigan in his article on 'The Prin ciples of Effective Radio Speaking 'in The Quar terly Journal of Speech The general rule most tactfully put, is 'a radio speaker should talk only so long as he is talking interestingly and well on a subject calculated to hold attention? corollary is, 'This may in some cases exceed ten or fifteen minutes' Perhaps many orators think they belong in the exceptional class but the professor goes on with a blow for that belief If a speaker is a Presidential candidate, or otherwise very well known, he may take liberties with the time of his radio audience. As for trying to hold them with jokes, that hope is dashed too speaker should never incorporate witticisms in his remarks unless he is listed on the program a humorist

"Speakers are told that they should assume the intelligence of the general public to be that of a 12 year old child. One studio has hung in a prominent place a picture of Mrs. Blank of Blank Street a workingman's wife with her babies. She is there to remind all performers that they are directing their entertainment or instruction at her.

"Because it is as yet impossible to reproduce or receive the sound of 'th' and s perfectly, speakers are advised to substitute crime' for halessness and 'gratifude for thanks'. One announcer was embarrassed because he neglected this rule. Broadcasting an annual convention at a large hotel, he told his audience that the grand ballroom was all filled with booths. That seem ingly innocent last word came out 'booze,' to the delight of some listeners and the fury of some 'booth holders'."

These remarks are of special interest to physicians since the great increase of medical broad casting by medical societies and departments of health

#### ROADSIDE FIRST-AID STATIONS

The New York Herald Tribune of June 9 had the following account of the extension of the first aid service of the American Red Cross

Plans under which Red Cross emergency firstaid service on the highways will be established in the campaign to reduce deaths from automobile injuries were announced today by James L. Fieser vice chairman in charge of domestic

operations
'The Red Cross, through its chapters, will establish emergency first aid service at suitable points along the highways where accidents have been frequent, or at junctions of main arteries Wayside stores community centers suburban stations of State Police, etc, are suggested as locations Local chapters are to assume responsibility for chains or these emergency stations at convenient intervals along the important roads within their jurisdiction. Supervision of the plan will be under H. F. Pallows national director of first and and life saving, at Red Cross headquarters here.

"Fach emergency station will keep on hand a complete kit of first aid supplies. An essential of the service to the injured will be a telephone

directory of physicians, hospitals and ambulance services in the immediate vicinity approved by the local medical society. At least one person trained in Red Cross first and always will be on hand

"Chapters are instructed to have volunteer automobile transportation for the injured, where necessary Road markers displaying the Red Cross symbol, and designating the distance to the first and station, are to be placed, if possible, one half mile from each station

"The service to be given to the injured motorist is a purely voluntary, humanitarian one. It comprises binding of wounds, calling a doctor and otherwise providing prompt assistance to the injured. No financial remuneration will be accepted for the service."

Physicians will be interested to see whether or not this service will be practical. Those injured in automobile accidents are notoriously ungrate ful. They impose on physicians and hospitals and refuse to pay their bills on the ground that the insurance companies are hable for them. Free services by the Red Cross will add to the financial confusion.

## BOOK REVIEWS

TULAREMIA. History, Pathology, Diagnosis and Treatment. By WALTER M. SIMPSON, M.S., M.D. Octavo of 162 pages, illustrated. New York, Paul B. Hoeber, Inc., 1929. Cloth, \$5.00.

This highly interesting and valuable work should be in every physician's library who would keep abreast of

the times.

The recent discovery of over 1,000 cases of this disease in different provinces of Russia through the medium of the infected vole or water rat (arvicola Amphibious) has furnished evidence that the disease is not confined to the United States and Japan, as has up to now been believed. The author writes with authority on the pathology of this disease.

The colored plates and photomicrographs are a great aid in this study. The history and bacteriology of this

disease are carefully reviewed.

The unusually large experience of 61 cases which the author has had in Dayton, Ohio, has given him exceptional opportunity for the study of the clinical characters of the disease.

He adopts the usually accepted classification into 4

different types, viz:

Ulcero-glandular Oculo-glandular

2.

Glandular

Typhoid

The reviewer has used the same classification in reporting a case seen in Brooklyn. He is inclined to agree, however, on further consideration, with a name-sake of the author, Virgil E. Simpson, of Louisville, Kentucky, that the oculo-glandular group of cases might be placed under the heading, ulcero-glandular type.

The primary lesion (ulcer) in the one case being on the conjuntiva instead of the skin, and hardly war-

rants a separate type.

The book under review is the first of its kind, and is destined to become a classic. W. Moser.

RECENT ADVANCES IN OPHTHALMOLOGY. By W. STEWART DUKE-ELDER, M.A., D.Sc., M.D. Second Edition. Octavo of 405 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, 1929. Cloth, \$3.50

Like the previous edition of this work and in fact, like so many of the books from our English brothers. the arrangement and diction of the present volume is

pleasing in the extreme.

The title would lead one to think of a work of this kind as only fitted for the advanced and mature student of ophthalmology. Perhaps this is true of some of the discussions, but others are very appropriate for the beginner. For instance, the section on biomicroscopy of the living eyes is very good material for the novice. It does not present the details of technique but describes the principles and applications in this new field with pleasing lucidity.

Beyond this field of usefulness, the work offers a valuable reference material for the laboratory, as the bibliography is placed at the end of the related chapter.

Though this volume comprises less than 400 pages, it seems to contain an unbounded number of interesting subjects so condensed as to be particularly attractive as a morsel of ophthalmic pabulum. For relaxation after a day of routine-it is always refreshing.

JOHN N. EVANS.

GASTRIC AND DUODENAL ULCER. BY ARTHUR F. HURST, M.A., M.D., and MATTHEW J. STEWART, M.B. (Glasg.), F.R.C.P. Octavo of 544 pages, illustrated. London and New York Office University Press 1999. Clark and New York, Oxford University Press, 1929. Cloth,

\$20,00.
This is a very complete work. It is not only monutental but very readable. The reviewer recommends mental but very readable. it to the surgeon, the medical man and the radiologist as being probably the best all around work on the sub-

ject that has yet been written.

It is becoming more common for men treating certain diseases to collaborate in their study. In this book a physician, a pathologist and a radiologist have collaborated in a most excellent manner. It is to be hoped that the next collaborators will include a surgeon.

There are chapters in the book which will be found particularly useful to the busy practitioner as the authors have gone quite minutely into the details of medical treatment. Certain paragraphs might well be copied and passed on to the patient for his better understanding of the treatment of his disease. It is a book which will be of value and interest to every surgeon, physician, general practitioner and student. The book physician, general practitioner and student. will also present many items of interest to the medical historian.

The reviewer wishes to quote a single paragraph which sounds the keynote of the book and which explains in part why he recommends this excellent book to such

a wide audience. The paragraph follows:
"We owe the enormous progress in our knowledge
of gastric and duodenal ulcer during the first twenty years of the present century almost entirely to surgeons. In the last eight years the bio-chemist and radiologist have added their quota. If they are prepared to seize their opportunity, the prevention, early recognition, and successful treatment of ulcer should in the future be in the hands of the general practitioner and the physician." RUSSELL S. FOWLER.

Medical: Clinics of North America. Vol. 13, Nos. 1 to 3. Published every other month by the W. B. Saunders Company, Philadelphia and London, Per Clinic Year (6 issues), Cloth, \$16.00 net; paper,

Volume 13, Number 1, July, 1929 (Boston Number): Some of the principal articles in this number are "Diabetic Coma," by Joslin and others, "Complete Pneumothorax," "Nephrosis," "Thrombo-Angiitis Obliterans," "Eclampsia" and "Subacute Bacterial Endoliterans," carditis." carditis," Joslin is all the more convinced that the administration of alkalies is unnecessary in diabetic coma. In the article on thrombo-angiitis obliterans the authors state their opinion that this disease should be regarded as one which affects the arteries and veins not only of the extremities but also of the cranial, thoracic, coronary and abdominal vessels.
Volume 13, Number 2, September, 1929 (Chicago

Number):

Some of the principal subjects considered are mediastinal disease, bundle branch block, arterial hypertension with electrocardiographic studies, and the treatment of pneumonia.

Volume 13, Number 3, November, 1929 (New York

Number):

Pardee contributes an interesting article on "The Importance of the Etiology in the Diagnosis of Heart Disease," and there are articles on pernicious anemia, serum treatment of pneumonia, nephritis, bronchial asthma, and numerous other subjects.

W. E. McCollom.

THE FEMALE SEX HORMONE. BY ROBERT T. FRANK, A.M. M.D., F.A.C.S. Part I. Biology, Pharmacology and Chemistry. Part II. Clinical Investigations Based on the Female Sex Hormone Blood Test. Octavo of 321 pages, illustrated. Springfield, Ill., Charles C. Thomas, 1929. Cloth, \$3.50.

Dr. Robert T. Frank's monograph on the "Female Sex Hormone" is a book containing 315 pages which is divided into two parts. The first half is devoted to the experimental investigations embodying the Biology, Pharmacology and Chemistry and the second half to the clinical investigations based on the Female Sex Hormone Blood Test.

The subject is thoroughly, completely and withal concisely covered. No subject is today more generally discussed than the subject of Female Sex Hormone. Much credit must be given to Dr. Frank for bringing this splendidly, illustrated monograph on an important and little known subject within the grasp of every

practitioner of medicine.

It is a gem to the scientific gynecologist and obstetrician, and a most handy volume to be treasured by every physician. PHILIP OGINZ.

A System of Bacteriology in Relation to Medicine. [By Various Authors.] (Prepared under the direction of the Medical Research Council.) Volume II. Octavo of 420 pages. London His Majesty's Stationery Office, 1929. Cloth, £8-8-0 a set; £1-1-0 each.

This system of bacteriology, comprising nine volumes, is the work of nearly one hundred British bacteriologists, each a specialist in his field. It is being prepared under the auspices of the Medical Research Council. The present, volume 3, is the first to appear. The aim is to present a comprehensive knowledge of bacteriology especially in relation to medicine.

About 130 pages are devoted to the economic aspects of bacteriology. This part should interest laymen and physicians as much or more than bacteriologists. It shows, in detail, the immense importance of bacteriology

in industry and agriculture,

The remainder of the volume is devoted to discussion of the following organisms: B. Pestis, the organisms of gas gangrene, B. Tetani, B. Butulinus and food of gas gangtine, B. Ietani, B. Dittilinus and 100d poisoning. Each organism is given the most comprehensive description and discussion. This includes history, morphology, cultural reactions, biochemistry, pathology in man and animals, immunology, symptomatology transmission, prevention and treatment. At the end of seath chapter is a page of reference to the literature. each chapter is a page of references to the literature.

each chapter is a page or references to the interature. The reviewer was particularly interested in the account of B. Pestis and the plague. This great scourge has always had a dramatic interest. The story of the discovery of B. Pestis and the pains-taking elaborate studies which led to the discovery of the exact mechanisms. ism of transmission of the infection from rats to humans and the story of rat migrations are as fascinating as any novel of human adventure.

If future volumes equal this one in interest and scientific value, this system will take a high place in medical literature. E. B. SMITH.

AN INTRODUCTION TO THE STUDY OF HUMAN ANATOMY, By Robert James Terry, A.B., M.D. Octavo of 345 pages. New York, The Macmillan Company, 1929. Cloth, \$3.50.

This book is a laboratory guide based on verification and research of the parts dissected. It is unusual and unique in that it endeavors to stimulate the student to do careful and neat dissection and then to verify the find-ings. Students of Anatomy in general, should have this work in the Anatomical laboratory while dissecting.

GAETANO DE YOANNA.

A PRACTICAL TREATISE ON DISORDERS OF THE SEXUAL FUNCTION IN THE MALE AND FEMALE BY MAX HUHNER, M.D. Third Edition. Octavo of 342 pages Philadelphia, F. A. Davis Company, 1929. Cloth, \$3,00.

This book of Doctor Huhner's is already familiar to the profession. It handles a group of subjects which are sadly neglected in most textbooks on Genito-Urmary Diseases, in a perfectly frank, open and capable manner.

Disorders of the sexual function constitute a very real and a very important group of pathological conditions, many of which are readily amenable to intelligent treatment. Dr. Huhner has broken down the barrier of prudishness and has discussed these problems openly and frankly, outlining in careful detail appropriate treatment where indicated.

The third edition has an added chapter on dysmenorrhea, in which he discusses the medical treatment of this symptom. It would seem to the writer that this chapter is a bit out of place and adds very little to the book. N. P. R.

DEVILS, DRUGS, AND DOCTORS. The Story of the Science of Healing from Medicine Man to Doctor. By How-ARD W. HAGGARD, M.D. Octavo of 405 pages, illustrated. New York and London, Harper & Brothers, 1929. Cloth, \$5.00.

Dr. Haggard has given us a history of medicine that is different. He has blended the ancient with the modern development of the healing art in a most fascinating

and interest-holding narrative.

The subject is not approached in the usual chronological or period order, nor does it center around those outstanding characters who have played such an important part in the evolution of medicine. The author has chosen some of the more important branches of medicine and builds his story of its progress around these divisions.

In Part 1, he describes the development of obstetrics. The discovery of anesthesia and the progress of surgery are presented in Parts 2 and 3. Part 4 tells the advances we have made in preventive medicine in conquering plague and pestilence. Our slow but onward march through superstition, magic, quackery and cultism of all kinds in the treatment of diseases, is unusually well covered in Part 5. The progress achieved in more recent times is credited in the concluding part to the coming of the scientific spirit and this must survive if medical science is to continue to exist and advance,

The text-matter is illuminated with a large number of quaint, old illustrations not frequenty to be found in books of this type. We venture to predict that this work will find a place among the best sellers in medical histories.

YNOPSIS OF MIDWIFERY AND GYNECOLOGY, BY ALECK W. BOURNE, B.A., M.B., B. Ch. (Camb.), Fourth Edition. 12mo of 434 pages, illustrated. New York, William Wood and Company, 1929. Cloth, \$4.50. Synopsis of Midwifery and Gynecology,

The fourth edition of this book has been thoroughly revised. Some new subject matter has been added, and other matter, which has become out of date, has been omitted.

The author intends that the book should serve as a useful supplement to, and as a substitute for, the ordinary text books, in order that the subject may be quickly reviewed for examination.

The sections on diagnosis and treatment are practical and concise, and the volume will undoubtedly be of value to general practitioners and to those who wish to quickly refresh their memories on this subject. W. S. S.

## OUR NEIGHBORS

#### THE MEDICAL SCHOOL AND THE STATE SOCIETY IN IOWA

Dr. Henry S. Houghton, Dean of the State University of Iowa, College of Medicine, Iowa City, discusses the relation of the Medical School to the Medical Profession in an article in the May issue of the Journal of the Iowa State Medical Society. Conferences held between the representatives of the Medical School and the medical society are described as follows:

"Certain steps have already been hopefully taken. During the summer and autumn of 1928, there were numerous meetings between groups representing this Society and the College of The officers and legislative committee responded cheerfully to frequent requests to meet and debate these baffling problems. Many points were agreed upon after long and frank discussion; that we were unable to dissolve all of the obstacles was due perhaps not so much to lack of goodwill or cooperation in either of the groups as it was to a lack of complete information on the one hand, and some uncertainty as to the will of the Society on the other."

The law provides for the care of indigent patients in the hospital of the State Medical School in order that the school may have clinical material for teaching purposes. Physicians have objected that patients not indigents were given free treatments. Patients are admitted only on the certificates of physicians, Dr. Houghton says:

"An expression of opinion from the examining physician as to the prospective patient's incapacity or otherwise to pay has been added to the medical certification. The Hospital is ready to furnish to the secretaries of all county societies a monthly record of all State patients committed from the county concerned, and by whom certified. These are some of the changes made. The Legislative Committee asked that they be incorporated into the basic statute, but the Board of Education was relucant to do so at once, for two reasons; in the first place, it seemed probable that further exploration would bring to light other desirable changes and additions which should eventually be made a part of the law, and in the second place, it was felt unwise to seek revision of the law until and unless a conclusive comprehensive and reciprocally acceptable policy has been determined. In the meantime the measures suggested in conference with the officers and committees of the Society were adopted as administrative procedures by the Board and put into use. I need scarcely remind you that the administrative regulations of the Board have precisely the force of law as far as the University Hospitals are concerned."

Concerning agreements between the school and the society, Dr. Houghton says:

"A unity plan and purpose, as between the State Medical Society and the College of Medicine is attainable, in my opinion, if three basic conditions can be fulfilled.

"First, we must know our ground thoroughly, and be in a position to discover and weigh the essential factors which are at issue. supposes that we have full information, and enough time in which to analyze it.

"Second, a common foundational program should be formulated, which would conserve enlightened self interest to all concerned.

"Third, a frank and friendly relationship must be developed.

"A unified program for progress might properly be defined as the welding of concerted effort in the fields of practice (curative medicine as personal enterprise) preventive medicine and public health, and the training of physicians and In each of these varying professional divisions independent progressive moves have been made, or are in the making, but thus far there has been little inter-relationship. The Society has been increasingly concerned with favoring wise legislation for safeguarding physicians and the public; it has also given support and encouragement to the work of the State Department of Health; it has in many ways helpfully assisted in the development of medical education. But it would appear that still more can be done, if the way is cleared, to attain the ideals toward which we look."

The relation of public health to the school and society is discussed as follows:

"The relationship of public health effort to medical education and to organized medicine should not be dealt with lightly. We have had a picture in conferences held during the autumn and winter of the bewildering multiplicity of organizations concerned with one phase or another of public health and welfare, often unrelated to each other, to the State Department of Health or to the medical profession-duplicating activities and working at cross purposes.

"An important step toward unity and progress in this vital field of public health would be to have a survey made by a thoroughly qualified disinterested expert, of all phases of such work being done in this State. This could be carried out under the auspices of the Governor; it could be accomplished without incurring the criticism of partisan bias, and it would serve as a guide

(Continued on page 748-adv. x)

#### The Pediatrician's Formula

The first suggestion for the preparation of Mead's Dextri-Maltose came from pediatricians. Naturally, their preference for this particular form of carbohydrate is back of its very conception. Dextri-Maltose brings mothers with their babies back to your office, not only because of its clinical results, but because it satisfies the mother that her baby is receiving individual attention—that it is getting "a formula".

From your viewpoint, this motherpsychology is all the more an important point of medical economics because there are no feeding directions or descriptive circulars in the packages of Dextri-Maltose. It is truly the 'doctor's formula.

DEXTRI MALTOSE NOS 1 2 AND 3 SUPPLIED IN 1 LB AND 5 LB TINS AT DRUGGISTS SAMPLES AND LITERATURE ON REQUEST MEAD JOHNSON & CO EVANSVILLE IND USA

## Dextri-Maltose for Modifying Lactic Acid Milk

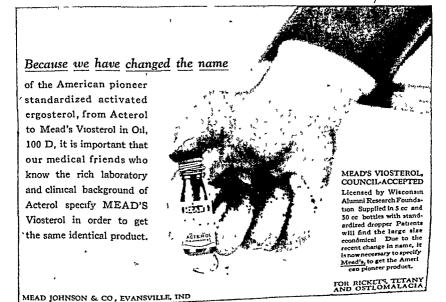

In using lactic acid milk for feeding infants, physicians find Dextri-Maltose the carbohydrate of choice:

To begin with, Dextri-Maltose is a bacteriologically clean product, unattractive to flies, dirt, etc. It is dry, and easy to measure accurately.

Moreover, Dextri-Maltose is prepared primarily for infant-feeding purposes by a natural diastatic action.

Finally, Destri-Maltose is never advertised to the public but only to the physician, prescribed by him according to the individual requirements of each baby.

DEXTRI MALTOSE NOS 1 2 AND 3 SUPPLIED IN 1 LB AND 5 LB TINS AT DRUGGISTS SAMPL'S AND LITERATURE DO REQUEST MEAD JOHNSON & CO EVANSVILLE IND US A

## "Upon the Advice of My Physician"

HE majority of men and women who come I to McGovern's Gymnasium to correct some physical condition are sent there directly by their physicians.

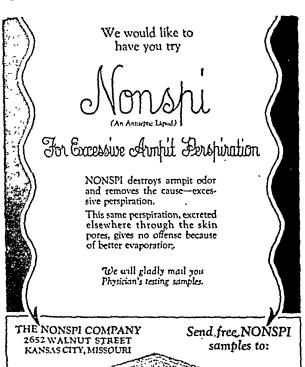

For more and more physicians are realizing the futility of leaving patients to their own resources when exercises are prescribed, and have learned that through individual attention at McGovern's, their instructions will be faithfully carried out.

A work-out will convince you of the superiority of the McGovern Method. Let us send you a guest card. No obligations, of course.

jovern's mnasium

(Continued from page 746)

for the objectives sought by the State Society, the State Department of Health, the wide group of non-official social welfare organizations, and

the University.

"This new step, together with the other items mentioned, will make clear, I hope, the fact that the College of Medicine faces hopefully and expectantly the prospect of relating more fully its educational and medical service program to the activities and interests of the State Medical Society and the State health agencies. The College of Medicine has no desire to stand apart from these great organizations, either in its policies or its acts; its vigor and success in the long run will ebb or flow according to the completeness with which this smooth and effective interworking is attained."

#### ANNUAL MEETING IN NEW JERSEY

The May issue of the Journal of the Medical Society of New Jersey describes the annual meeting of the Society editorially as follows:

"For many reasons, the Annual Meeting to be held June 11 to 14 at Haddon Hall. Atlantic City, should be of interest to every member of this society. Not only is it the annually recurring event to which so many of us look forward expectantly and pleasurably-the 164th convention of the oldest state medical society in the United States-but it is the most important gathering of the year for physicians practicing in this region. Each succeeding year this organization takes on a new degree of vital influence in our lives. It is here that plans are proposed, policies discussed, decisions made, that determine the relation of the physician to the community and that to a large extent shape his destiny. The science of medicine is considered and recent discoveries and advancements are reported or reviewed. Yet, but perhaps of even greater importance is the fact that the art and the business of practice is given a deal of consideration. Medical sociology has a more vital interest for physicians today than has medical science; and it is each member's duty, to his profession and in his own self interest, to participate in the consideration, the development and the guidance of changing medicosocial conditions.

"Look over the program presented in this issue of the Journal and note how it affects you. More than twenty-five purely scientific topics scheduled; one separate and distinct afternoon session devoted to problems of the School Physician; one afternoon session at which the Chiefs of State Departments will describe the extent to which the state is now involved in the practice of medicine; one ses-

(Continued on page 749-adv. xi)

(Continued from page 748-adv. x)

sion at which distinguished visitors from other states will direct attention to the larger, national trends in medical thought and work.

"Then, there will be profitable side-shows. In a room near the Exhibit Hall, a continuous showing of scientific moving pictures will be presented. In another room we hope to exhibit some of the work of a few members, who, as a diversion from professional labors, engage in the "fine arts"—painting, etching, modelling, sculpture.

"Nor has your social entertainment been neglected. A "Dinner Dance" on Friday evening, under management of the Woman's Auxiliary, promises to be a gala affair; it should be, with good food, splendid music, beautiful

women, and dreamy dances."

### MEDICAL SCHOOL OF MISSOURI

The May issue of the Journal of the Missouri State Medical Association discusses the expansion of the two-year medical instruction in the Missouri University at Columbia so that the full four-year course may be given. The report of a State Survey Commission says:

"The Missouri State Medical Association on more than one occasion has adopted resolutions insisting that adequate facilities be provided at Missouri University to enable a student to complete his four years of medicine. This faction also points out that medical schools keep their enrollment up to capacity and that a student finishing the two years offered at the State University cannot choose the school to which he wants to go for the final two years. His entrance must be arranged for by the school at Columbia. The faction also calls attention of the Commission to the fact that the school of medicine of the University has an organization for a four-year course, that there is a well-selected library and valuable laboratory equipment. This faction says that at the present time the job of medical education is only being half done by the University.

"Dr. George D. Strayer and associates, of Columbia University, New York, who were invited by the Commission to assist in making the survey, were very vigorous in the opinion that Missouri should have an adequate medical school. They pointed out that during 1929 there were 459 Missourians pursuing medical education in the United States and that 55 per cent of them are in schools in Missouri while, in the four states mentioned, from 74 to 78 per cent of the prospective physicians are students in their own states. Dr. Strayer urges the establishment of a large state hospital at Columbia to serve the

rural population of the state and to furnish clinical facilities for the medical school.

The other faction thinks that with two medical schools in St. Louis, one in Kansas City, Kansas, and one at the University of Iowa, there is no necessity for the expenditure entailed in establishing the four-year course. This faction points out that a state hospital in Columbia would be required to provide clinical facilities for the medical school, but because of the proximity of the schools mentioned the erection of such a hospital and the extension of the school to a course of four years were deemed needless. The faction seems to have entirely overlooked the extreme difficulty the two-year student encounters in entering desirable schools, not only in Missouri but throughout the country.

"The Commission very definitely asserts that it has not adopted any of these recommendations. It merely submits them for the consideration they merit. The Commission expressed the view that if an endowment could be obtained which would be adequate to erect and support a hospital program at Columbia, the State should make the necessary appropriations to maintain and support the medical school at that institution."

## MEDICAL STUDENT LOAN FUND IN NEBRASKA

Loans to worthy medical students are discussed in the following editorial in the May issue of the Nebraska State Medical Journal:

"It may be safely assumed that it is no crime for a poor boy with ambition to aspire to a medical education. One must admire the courage of the poor youth whose soul is fired with the ambition and who has the courage in spite of the handicap of a lack of sufficient means, to undertake the task involved in pursuing a medical course requiring six or seven years to accomplish when funds are provided. The old saying, 'Where there is a will there is a way,' is still apt. Medical educators as a class are thought to discourage the poor boy undertaking a medical course; but ambition is not so easily squelched and every year each medical school probably has some entrants without sufficient means to complete the course. It has been thought that in some schools this class of students runs up to ten per cent of the total registrants, which may be a high figure. The writer has heard of a young man who worked himself through Harvard and an interneship in twelve years. There are those who wait table, stoke furnaces and room in physicians' offices answering night calls for a part of their subsistance and rooms. While

(Continued from page 750-adv 111)

such tremendous handicaps must affect scholarship to a degree, it must develop self reliance and character—assets of great value in later life. High scholarship alone does not make the successful practitioner as we all know. Some of the most noted men in medical history have records of indifferent scholarship.

"The problem of the needy and worthy student has appealed to humanitarian agencies from time to time and efforts have been made to render financial assistance to those of good scholarship in the Senior year; some in the Junior and Senior years, With the required interneship year the problem of assisting in-

ternes has been added.

"Several agencies assist worthy, needy students in the Omaha medical schools, notably the Nebraska Federation of Woman's Clubs. The need, however, exceeds the resources of

the funds provided.

"No doubt the membership of the Nebraska State Medical Association is as much interested in this problem of needy students as the Federation of Woman's Clubs and the Association at its annual meeting might do well to consider creating such a Fund."

#### CANCER COURSE IN PENNSYLVANIA

The May issue of the Pennsylvania Medical Journal contains the following description of a cancer course to be conducted at Harrisburg on June 4, under the auspices of the Dauphin County Medical Society and sponsored by the Medical Society of the State of Pennsylvania through its Cancer Commission of which Dr. J. M. Wainwright of Scranton is chairman.

"A registration fee of three dollars will be charged, which will include the informal dinner at the evening session to be held at the

Penn Harris Hotel.

"The physician must bear in mind that he sees the cancer patient first, and upon his alertness and keen perception depend the making of an early diagnosis. He should know, too, what to advise the patient, when early diagnosis has been made. If the morbidity and mortality of cancer is to be reduced, early recognition and prompt and proper treatment must be instituted. When a patient does not consult the physician in time to make an early diagnosis, the physician is not to be blamed. On the other hand, the physician must appreciate that much of his work involves preven-

(Continued on page 752-adv. xiv)

Alka-Zane is a granular, effert escent salt of calcium, magnesium, sodium, and potassium carbonates, citrates and phosphates. Dose, one teaspoonful in a glass of cold water.

WILLIAM R. WARNER & COMPANY, Inc.

113 WEST 18th STREET NEW YORK CITY

## The stomach does not stand alone

EXCESSIVE acidity of the stomach may be a signal of a depleted alkali reserve. It is not enough to neutralize the gastric acidity. Systemic alkalization is necessary for permanent results.

Alka-Zane is so prepared that it neutralizes gastric acidity promptly but not excessively, and so does not interfere with the digestive function of the stomach. Its full action is obtained after absorption.

Final decision on the true worth of Alka-Zane rests with the physician. We will gladly send a twin package, with literature, for trial.

Alka-Zane

rural population of the state and to furnish clinical facilities for the medical school.

"The other faction thinks that with two medical schools in St. Louis, one in Kansas City, Kansas, and one at the University of Iowa, there is no necessity for the expenditure entailed in es-This faction tablishing the four-year course. points out that a state hospital in Columbia would be required to provide clinical facilities for the medical school, but because of the proximity of the schools mentioned the erection of such a hospital and the extension of the school to a course of four years were deemed needless. The faction seems to have entirely overlooked the extreme difficulty the two-year student encounters in entering desirable schools, not only in Missouri but throughout the country.

"The Commission very definitely asserts that it has not adopted any of these recommendations. It merely submits them for the consideration they merit. The Commission expressed the view that if an endowment could be obtained which would be adequate to erect and support a hospital program at Columbia, the State should make the necessary appropriations to maintain and support the medical school at that institution."

## MEDICAL STUDENT LOAN FUND IN NEBRASKA

Loans to worthy medical students are discussed in the following editorial in the May issue of the Nebraska State Medical Journal:

"It may be safely assumed that it is no crime for a poor boy with ambition to aspire to a medical education. One must admire the courage of the poor youth whose soul is fired with the ambition and who has the courage in means, to undertake the task involved in pursuing a medical course requiring six or seven years to accomplish when funds are provided. The old saying, 'Where there is a will there is a way,' is still apt. Medical educators as a class are thought to discourage the poor boy undertaking a medical course; but ambition is not so easily squelched and every year each medical school probably has some entrants without sufficient means to complete the course. It has been thought that in some schools this class of students runs up to ten per cent of the total registrants, which may be a high figure. The writer has heard of a young man who worked himself through Harvard and an interneship in twelve years. There are those who wait table, stoke furnaces and room in physicians' offices answering night calls for a part of their subsistance and rooms. While

its duty by the Health Department, or lack of funds appropriated by the state. If ours be the fault, it would seem an easy situation to control It only requires that the practicing physician promptly report each birth attended by hun, on blanks furnished by the State Department of Health, and to officials easy of access to him. How simple! It only requires that the physician burden his memory to a minimum extent, and spend a few moments time in making inquiries and filling in the blank The law requires that he do so. To fail to do so is to violate the law. The law was passed at the instance of the organized medical profession of this state. It has recently been amended upon our suggestion, and now it remains for us to see that it is enforced, at least to the extent that we may take our place among the other states of the United States in offering every opportunity to our health workers to solve the many and intricate problems pertaining to the very important matter of the health of our people

"The increase in registration in Texas indicates a splendid response on the part of the profession to the law passed at the request of the State Association, and although, according to the figures in other states and the rates used by the federal government, there should be more than 130,000 births and 65,000 deaths per year in Texas, the admission of a state to the Registration Area is not based upon rates, but upon an investigation as to the actual number of births and deaths which have occurred, and it is hoped that such an investigation will not find obstetricians and hospitals rated as A-1, failing to observe the requirements of birth registration will be noted that the totals are considerably short. We certainly can do better than that.

Let us see to it that we do. "According to the figures in other states, and the factors used by the federal government in getting at the matter, there should be approximately 130,000 births per year in Texas. That means that we must record 117,000 births per year to get in the Registration Area. Last year there were 97,991 births registered It will be noted that this is considerably short of the re-We certainly can do better than that. Let us see to it that we do.'

#### CRIPPLED CHILDREN IN IOWA

The May issue of the Journal of the Iowa State Medical Society contains the following editorial on a survey of crippled children in Towa under a law similar to that of New York State.

"Through the office of the Superintendent of Public Instruction we have been advithis

Department is now engaged in preparing a census of the physically and mentally handicapped people in the State of Iowa between the ages of five and twenty-one, as directed by the last session of the general assembly. This survey is to include both those in and out of school. County superintendents of schools will organize the teachers in each county to list those known to be defective, and the reports will be based upon the local school district as a unit. The director of this work is very anxious that this list shall be as complete as possible, and that the data assembled shall be based on more than the opinions

or observations of the teacher.

"With this in mind, an appeal has been made to the members of the Iowa State Medical Society to assist in the program, since it is realized that through the activities of the Society and those of its individual members, distinct contributions to the solution of many problems of the school child have been made. They further realize that the members of the State Society are prepared and equipped to determine the extent of physical defectiveness much more accurately than a lay person. It is hoped that the school teachers and superintendents will have the cooperation of the medical profession in this work in making the returns accurate and comprehensive, and that physical examinations may be secured when required through the members of organized medical units. Mental diseases should be reported as well as physical ones in this survey. They will be given special listing and classification.

"Special instructions as to the nature of the handicaps to be reported and how each type is defined in this census are now being sent to all schools through county superintendents and physicians. Those interested in the matter may receive full instructions from this source. Further information relative to the program may be secured from the county superintendent of instruction in your county, or by directing your inquiry to the State Department of Public Instruction in Des Moines.

#### OSTEOPATHS AS HEALTH OFFICERS IN WASHINGTON

The March issue of Northwest Medicine comments editorially on the appointment of an osteopath as health officers in the State of

Washington as follows:

"When the city council of Ellenburg a year ago appointed as health officer Walker, an osteopath, the incumbent physician, Dean, refused to retire and turn over the office to the new appointee. This was in accordance with instructions from the Washington State Board o' Health, on the grounds that an osteopath is net a 'legally qualified physician.'

(Continued on page 755-adv. xvii)

(Continued from page 754-al vii)

"In April, 1929, Walker appealed to the su perior court in Kittitas county which confirmed the action of the state board of health in refusing his appointment as health officer Later he appealed from this decision to the State Supreme Court The case was heard by five of the nine members of the court, and on February 3 of this year an opinion was rendered by Judge Walter B Beals with the concurrence of the other four, reversing the action The argument was of the superior court wholly on the ground that the term physician had of late years been broadened to include the osteopath, who is thus recognized as a physician in the same classification as a doctor of medicine as regards appointment to official positions in the state

"How can an ostcopyth as health officer direct the treatment and prophylaxis for diseases by methods which are denied to him in practice and with which he has had no experience? The situation amounts to a manifest absurdity. If he were to attempt to function as a health officer, he would be liable to prosecution as a law breaker for failure to carry out the requirements provided by health regulations in dealing with contagious diseases. Considering all aspects of this matter, one cannot avoid the

conclusion that the supreme court decision has been unwisely adopted. It is believed that this may be reconsidered and arguments may be entertained in accordance with these facts.

#### GRADUATE COURSES IN NEW JERSEY

"It is very pleasing to report that the special post graduate courses in medicine and surgery bring offered by the Medical Society of New Jersey through Rutgers University have been received by our members even more cordially than had been anticipated. The special committee having this matter in charge and the representatives put into the field by Rutgers have worked assiduously to launch the project sitisfactorily, and their labors have been rewarded by a hearty response. The committee will make a detailed report to the House of Delegates at the Annual Convention, with recommendations as to continuance of such study courses in the future, but we are per-

#### HOSPITALS IN OKLAHOMA

The May issue of the Journal of the Oklahoma State Medical Association contains the annual The reports of the officers Committee on Hospitals says

"The hospital has been called a Clearing House of Medical Science and such it should be Besides serving the people of the community in the conservation of health and life, the hospital is supposed to be an institution in which all the reputable physicians can meet on equal terms and share their experiences and their wisdom, thus making for the mutual improvement of the physicians themselves and their services to the people of the com-This is a fine ideal and munity it seems to be most nearly realized in those localities, cities or towns, where the hospital is a community institution

"The ill health of our citizens, accident, disease and poverty are a community affair-a common burden on all our citizens, and the institutions and instruments with which to cure these ills should be public property, in the same way as are our city halls and courthouses, fire stations, our public schools, municipal electric lighting and water plants Only so can the burden of sickness be equalized among all the citizens Under present conditions the burden is borne, (1) Largely by physicians who give unlimited gratuitous services, (2) By the unfortunate patients, whose illness is often no fault of their own, but of circumstances and environment and untoward conditions for which even society as a whole may be responsible, (3) By the voluntary contributions of philanthropic citizens The only way to correct abuses is to change the attitude of the public

"Some few hospitals are opcrated by men whose qualifications are mostly a knowledge of the advertising value of propaganda and the association of ideas in the mind of the public are operators rather than surgeons I A well known Urological Tournal says:

"If you must use a diuretic, try the best -water"

This recommendation is well worthy of adoption especially

ıs used. ¶ Physicians have commented favorably on its bland diuretic properties for over 60 years

Literature Free on Request

POLAND SPRING COMPANY Dept. C 680 Fifth Avenue New York City

-but this fine and vast difference the dear public is slow to grasp

"The outlook is not hopeless, however There are hopeful trends and tendencies If we of the hospital protession will clear our vision the public can be grad ually brought to right action But only by our cooperation will the hospitals gain the proper support of all the citizens

#### **EXAMINATION** HEALTH IN NEW JERSEY

The May issue of the Journal of the Medical Society of New Jersey contains the following item copied from the Hackensack Hospital Bulletin of April

"There is always new work for the hospital and its physicians to take up. A new need arises and is met

"Have a health examination on your birthday" is a slogan being broadcast throughout the nation Prolong your life by conserving it Avoid the pitfalls of old age and disease by proper living Frequent check-ups reveal little defects before they become scrious

#### Room Outfitted by Physicians

"The hospital has provided a room near the main entrance which is available for complete medical examinations been furnished with equipment donated by the following physicians I S Hallett, A R. Spiegelglass, Howard Cooper, P F Liva, S T Hubbard and S T Snedecor

"Doctors may now bring patients to this room for careful and complete examinations if they do not have the facilities in their offices Here the laboratory, a ray, and other technical aids are at their service if special tests are required "

## THE MEDICAL DIRECTORY

THE MEDICAL DIRECTORY OF NEW YORK, NEW JERSEY AND CONNECTICUT contains 910 pages of text relating to the individual doctors. It also has 48 pages of advertisements containing the announcements of 58 dealers and institutions on whom physicians depend for service and supplies, from abdominal supporters to X-ray apparatus. Patronize them whenever possible. They are reliable and appreciative.

## SATISFYING HUNGER in DIABETES

When you prescribe for a diabetic patient keep in mind the efficacy of Knox Gelatine as an agent for satisfying appetite without violating the most rigid protein diet.

Here is the purest of gelatine, uncolored, unflavored and unsweetened.

It may be combined with such fruits, vegetables, and other foods, as are prescribed for a diabetic patient—and served as a dish so appetizing in taste and appearance, so satisfying in bulk, that the most eager appetite will find itself happily abated.

Recognized dietetic authorities have prepared dishes made with Knox Sparkling Gelatine. that are a real contribution to the successful treatment of diabetes. Here are two recipes that will aid you in giving diabetic patients complete instructions for home co-operation with your treatment.

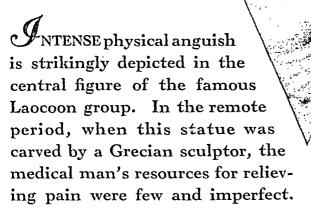

# KNOX is the real GELATINE

Contains No Sugar

# SELLIED VEGETABLE SALAD (Sie Sereiner) 1 tablespoon Knon Spathing Cristum Frot. Fat Carb. Cal 1 (cup cold water. 1) (cap cold water. 1) 1 (cap cold water. 1) (cap cold water. 1) 1 (cap cold water. 1) (cap cold water. 1) 1 (cap cold water. 1) 1 (cap cold water. 1) 1 (cap cold water. 1) 1 (cap cold water. 1) 1 (cap cold cater. 1)

Soak gelatine in cold liquid for five minutes and dissolve in her broth. Season with salt and pepper and chill until nearly set. Falt in chicker and whipped cream. Turn into molds and chill until form. Serve on letture or garnlih with parsley and strip of pimente.

Nowadays the physician has at his disposal a large number of analgesics, and among these Pyramidon occupies a prominent place.

For more than thirty years, Pyramidon has proved a prompt and potent analgesic. The effect of a single dose often persists for many hours. Pyramidon does not disturb the stomach and is free from depressing action upon the heart and respiration.

Indications: Pyramidon has dem-

onstrated its efficiency as an analgesic in many painful conditions—frequently even wherenarcotics might otherwise be required. Especially good results have been obtained in headaches and neuralgias, in migraine, sciatica, lumbago, dysmenorrhea, tabetic pains, colds, influenza, and gouty rheumatic affections.

Dosage: The average dose for an adult is 5 grains, repeated if pain recurs; for children of 5 years, 1½ grains.

How supplied: Tablets of 5 grains (in tubes of 10 and bottles of 100), and 1½ grains (in bottles of 25 and 100). Elixir of Pyramidon, 2½ grains to the teaspoonful (in 4 oz. bottles).

Sample of Pyramidon tablets or Elixir on request

### When Your Diagnosis of Malignancy Has Been Confirmed We Can Help You

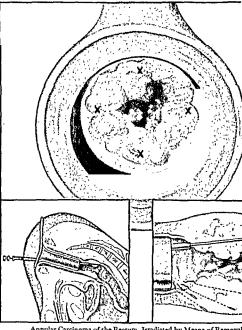

QUIETLY, but effectively, The Radium Emanation Corporation has been administering the radium needs of America's most prominent physicians since 1922.

We offer you the same technical counsel, the same extraordinary radium laboratory facilities that have made it possible for surgeons, gynecologists and urologists throughout the United

States and Canada to reinforce their own efforts in behalf of the patient afflicted with cancer.

Very definite changes have taken place in the art of radium therapy. The "hazard and hope" methods of earlier days have been abandoned in favor of a new, more scientific technique, which has completely changed the attitude of the entire medical fraternity towards the surgical use of radium, and radium therapy is rapidly becoming an indispensable element in the armamentarium of every surgeon, gynecologist and urologist.

The Radium Emanation Corporation has contributed in large measure to this modern trend in radium therapy. It gave the medical profession the Removable Platinum-Radon Seed which has made possible so many of the unparalleled results reported recently in the medical press. Through its radium therapy consultants. The Radium Emanation Corporation sponsors the most advanced methods in radium therapy and makes radium available to the individual physician according to the requirements of his particular case.

Annular Carcinoma of the Rectum, Irradiated by Means of Remova Platinum-Radon Seeds, Without Radical Surgery.

We have only one ideal—to help you obtain better results in the treatment of your malignant cases.

If you have malignant cases, for which you are considering treatment, investigate this unique service. Let our radium therapy consultants collaborate with you in the solution of your problems. They will gladly give you the benefit of their own broad experience and you may have their opinion and recommendations without incurring the slightest obligation.

Send us a history of the case and you will receive immediately a carefully considered plan covering the application of radium.

The type of service we are giving the medical profession will amaze you, unless you are one of the hundreds of physicians whose radium needs we are already administering.

Intense physical anguish is strikingly depicted in the central figure of the famous Laocoon group. In the remote period, when this statue was carved by a Grecian sculptor, the medical man's resources for relieving pain were few and imperfect.

Nowadays the physician has at his disposal a large number of analgesics, and among these Pyramidon occupies a prominent place.

For more than thirty years, Pyramidon has proved a prompt and potent analgesic. The effect of a single dose often persists for many hours. Pyramidon does not disturb the stomach and is free from depressing action upon the heart and respiration.

Indications: Pyramidon has dem-

onstrated its efficiency as an analgesic in many painful conditions—frequently even where narcotics might otherwise be required. Especially good results have been obtained in headaches and neuralgias, in migraine, sciatica, lumbago, dysmenorrhea, tabetic pains, colds, influenza, and gouty rheumatic affections.

Dosage: The average dose for an adult is 5 grains, repeated if pain recurs; for children of 5 years, 1½ grains.

How supplied: Tablets of 5 grains (in tubes of 10 and bottles of 100), and 1½ grains (in bottles of 25 and 100). Elixir of Pyramidon, 2½ grains to the teaspoonful (in 4 oz. bottles).

# Quick Relief

NOT only does the balanced antacid, BiSoDoL, afford quick relief to the well known symptoms of gastric hyperacidity, but it introduces a control factor against the setting up of a dangerous alkalosis—a chief objection to single alkali medication.

In BiSoDoL the sodium bicarbonate, being soluble, is immediately neutralized. However, as soon as neutralization has been established, magnesium carbonate serves as a control. It remains inert until a rise in the acid content of the stomach activates this neutralizing property. The two salts maintain the balance of normal reaction in the stomach, and correct abnormal deviations.

BiSoDoL has been found effective in controlling cyclic vomiting, the morning sickness of pregnancy, and alkalinizing against colds and respiratory affections.

In the formula are included bismuth subnitrate, antiflatulents and flavorings which enhance its value and render it acceptable to the patient.

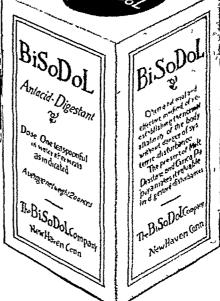

Advertised solely to the medical and allied professions.

Let us send you literature and sample for a clinical test.

# When is Diathermy of Value in Your Practice?

YOUR decision to use diathermy in the treatment of any condition will, of course, be based on recognized medical authority. Many physicians have become interested as a result of observing the many references to diathermy in current medical literature, and no doubt intend to investigate for themselves when opportunity presents. But a busy practice affords little of the time required in searching the files of the medical library, and it is put off indefinitely.

A preliminary survey of the articles on dinthermy, published during the past year or so, is available to you in the form of a 64 page booklet entitled "In dications for Dithermy' In this booklet you will find over 250 abstracts and ex tracts from articles by American and foreign authorities, including references to more than a hundred conditions in the treatment of which the use of diathermy is discussed

If you number yourself among the phy sicians who have not adopted diathermy in practice, and desire to investigate this form of therapy in view of reaching your own conclusion as to its value in your practice, you will find this booklet a conve-

nient reference A copy will be sent on request

# The Action of NEUTRALON

A synthetic aluminum silicate with about twelve per cent sodium silicate

DOSAGE: The usual dosage of Neutralon is a teaspoonful stirred in half a glass of water three times daily, before meals when the protective and astringent action is required, and after meals as an antacid.

#### ORIGINAL PACKAGES:

NEUTRALON

Boxes containing 50 and 100 grams.
Belladonna-Neutralon
Boxes containing 100 grams.

#### Belladonna-Neutralon

is Neutralon with the addition of 0.6% extract of belladonna.

#### Antacid

Neutralon has a twofold antacid effect, a siight immediate effect through the action of the soluble sodium silicate component and a slow prolonged effect through the decomposition of the insoluble aluminum silicate which converts free into combined acidity.

#### Astringent\_

The aluminum chloride formed by the reaction of Neutralon with the acids of the stomach acts as a mild astringent, thus tending to limit gastric secretion.

#### Adsorptive

Neutralon and the silicic acid adsorb albumen and pepsin so that the harmful digestive action of pepsin on the ulcerated wall of the stomach is hindered.

### Protective and Analgesic

Unchanged Neutralon and the silicic acid formed during the course of the reaction tend to form a coating on the ulcerated wall of the stomach, thereby affording protection against mechanical and chemical irritation.

Sample and literature upon request

### \$50.00 Saved on McIntosh Polysine During June

During April the price of copper dropped temporarily causing a reduction in price of brass wire and other materials entering the construction of the Polysine. At this particular juncture our Purchasing Agent found that one of the brass mills had a large surplus of the particular sizes of material used for the Polysine and was able to drive an exceedingly sharp bargain securing this material far below cost the outcome of the transaction being that 250 Polysine Generators were immediately placed in production resulting in a considerable reduction in manufacturing cost

#### How You Can Benefit by This

In order to pass along the benefit of this saving to the profession our General Sales Manager authorized a reduction of \$50.00 on each of these 250 Polysines to all purchasers sending in their orders together with the initial deposit of \$25.00 postmarked on or before June 30th Should they be all disposed of however before that date this special reduction immediately entires.

#### Unusually Easy Terms of Purchase

Will be extended to all purchasers under this special arrangement. Buy a Polysine now and reap the benefit of this \$50.00 saving. Utilize the unquestioned there peutic value of Galvanism and the Sinusoidal Currents as an aid in your practice and procure the same auccessful results as thousands of your confreres

GLUCOSE intravenously is used in surgical acidosis and shock, toxemias of pregnancy, in pneumonia and other infectious diseases. It also has indications in diseases of the heart, skin, and liver, in mercury and phosphorus poisoning, and cerebral edema.

Glucose intravenously is a source of food and energy, contributes to glycogen storage, conserves body tissues, prevents or overcomes dehydration, dilutes circulating toxins, acts as a diuretic, and relieves localized edemas.

Lilly Glucose Ampoules (Dextrose, U. S. P. X.) containing respectively 10, 25, and 50 grams of glucose in approximately 50 percent solutions are supplied through the drug trade.

#### SOME NEUROSURGICAL PROBLEMS OTHER THAN TUMORS AND ABSCESSES\*

By HENRY WARD WILLIAMS, M.D., FACS, ROCHESTER, N. Y.

A consideration of a variety of neurosurgical conditions is approached in the belief that during the brief twenty years span of the development of this branch of surgery there has not been sufficient general realization of its attainment to a level of satisfaction compirable to other branches. In the further opinion that this is more particularly true of actian conditions other than tumor and abscess these two subjects are not included in this brief presentation.

CRANIAL FRAUMA This subject of general interest presents a number of points worthy of discussion In the first place it is well to emphasize the fact that the chief factor in trauma to the head is the degree of injury to the nervous tissue, the amount of damage to the skull being of comparatively minor importance The injury to the brain may be simple concussion which is manifest by temporary loss of consciousness or there may be contusion or actual laceration of the brain, producing sympton's corresponding with the extent or location of the injury. Hemorrhage is also of importance because it produces immediate damage by clot formation or remote damage by interference with the flow of spinal fluid in the subarachnoid space through the production of adhesions

If the trauma is of sufficient magnitude an increase in intra cranial pressure results, which is merely a swelling of the brain due to an increase of fluid or blood or both and is essentially similar to swelling produced by bruising any other part of the body. The inclustic skull crists can not accordate more than a moderate amount of swelling and after the subarachnoid space is filled further expansion is impossible. Beyond this point the condition is made worse by the pressure shutting off the return circulation of blood from the brain, the

The treatment of head minutes consists al most entirely in the control of this one factor For this reason we have come to regard the level of consciousness as an indicator of the amount of intracranial pressure and the most important prognostic sign. Dehrium following injury should not be classed with unconscious ness and does not of itself suggest a graver prognosis Definite unconsciousness continued does make the outlook bad and until the level of consciousness rises to approximately normal energetic treatment of intracranial pressure is indicated It has been found that the introduc tion of concentrated (hypertonic) saline or glu cose solutions into the blood stream will de crease the volume of the brain by osmotic action drawing out fluid. The fluid thus drawn into the blood stream may be eliminated from the body by the use of a saline cathartic such as magnesium sulphate. As saline solutions produce a secondary rise of pressure after the salt has passed into the tissues which it will do after a time reversing the osmosis glucose seems to be preferable as it is destroyed in the blood stream and can not have that effect has been our custom to treat such cases with intravenous doses of 100 cc of 50% glucose solution once or twice a day and to give 12 ounce of magnesium sulphate every two hours by mouth or instilled in the rectum if the prtient cannot swallow This is, of course de creased as the condition improves. Daily spinal puncture assists in reducing pressure and also removes the blood which is almost always present in the spiral fluid. There is little question that blood allowed to remain in the question that blood allowed to remain in the cultural health of the cu spinal fluid produces changes in the subarach

attend blood which has pressure enough to still flow in stagnating in the veins before it can escape again. When this occurs the effect on the patient is to produce a depression of the level of consciousness, which if unrelieved spontaneously or by artificial means will progress to coma and death

<sup>\*</sup> Read at the Annual Meeting of the Medical Society of the State of New York at Utica N Y June 5 1929

noid spaces which may permanently upset the spinal fluid circulation.

Decompression. In a very occasional case is subtemporal decompressions indicated. Only in those cases where intracranial pressure remains elevated in spite of the above treatment. It is never wise to operate for the relief of intracranial pressure until dehydration treatment has been given a thorough trial. Following this rule will eliminate utterly useless operations in hopeless terminal stages of intracranial injury. No case which can not be controlled at all by dehydration can be saved by surgery, and one cannot help but have the feeling that operating because there is nothing else to do accomplishes nothing more than to discredit surgery.

EXTRA-DURAL HEMORRHAGE: Intracranial pressure may be raised by intracranial bleeding alone. If this bleeding is massive and inside the dura death occurs at once without the possibility of surgical intervention. is outside the dura recovery will occur if surgery is resorted to immediately. This being the only complication following head injury in which delay in operative interference is not preferable to haste. The condition of extradural clot is usually caused by a fracture through the middle fossa tearing a branch of the middle meningeal artery, and may follow a seemingly trivial injury. The following characteristic symptoms are observed. After the accident there is a lucid interval of a few hours during which examination of the patient reveals nothing abnormal. Then the patient becomes rather rapidly drowsy and unconscious, there is marked slowing of the pulse and weakness with exaggerated reflexes and a Babinski sign on the side of the body opposite to the clot. In the terminal stage convulsions occur on that side. The operation of choice for removal of the clot is a bone flap turned down to expose the clot. This is preferable to a subtemporal decompression through which the bleeding point cannot always be found. presence of the clot between the skull and the dura makes a flap operation easier than usual because the dura is pushed away from the bone and does not have to be avoided as carefully as is customarily the case.

SUB-DURAL HAEMATOMA: Bleeding within the dura if arterial is almost immediately fatal. If venous it is either absorbed or a clot formed. The symptoms differ from those of extra-dural bleeding most markedly in that the lucid interval may be from a few weeks to several months in duration. The clot commonly known as sub-dural haematoma lies over one side or other of the brain, its characteristic symptom is intractable headache gradually followed by pe-

riods of drowsiness continuing to unconsciousness. There is a very slight weakness of the side of the body opposite to the clot and a Babinski sign on that side, but convulsions seldom occur. There is usually some congestion of the fundi without definite choked disc being present. The spinal fluid is customarily and paradoxically under normal pressure with a slight increase in the cell count.- The clot is sharply outlined and of a dark greenish color. Its treatment is surgical and its approach varies with the age of the clot. If it is of short duration it will be found to be firm and must be removed entire through a bone flap. Whenit is older it will be softened in the center and its cure can be effected by the simple evacuation of the fluid center of the clot through a small burr hole. Once removed or evacuated the bleeding does not recur. These cases are not uncommon but are rarely diagnosed before death. The chief reason, for this is that the trauma is remote and frequently forgotten or not mentioned. This is unfortunate because few surgical diseases make a more rapid and complete recovery than a properly handled sub-dural clot.

PNEUMATOCELE: Aside from the presence of a blood clot within the cranium, intracranial pressure may be raised by the presence of air. It sometimes happens that in fracture through the anterior fossa the dura and skull are injured in such a way that air can enter the sub-dural space from the frontal or ethmoid sinuses. If the air can readily escape again the situation is only manifest by the discharge of spinal fluid from the nose. However, if the dura is so torn that it acts as a flap valve, the air which enters cannot escape. Coughing, sneezing, or blowing the nose forces air in faster than it can be absorbed. The pocket of air thus formed compresses the frontal lobe (See Figure 1) and produces a cyst like cavity which finally ruptures into the ventricle. A great part of the spinal fluid may be replaced by the air before death ensues. Clinically the symptoms are a discharge of spinal fluid from the nose followed in a few days by headache Any fracture involving a and drowsiness. sinus should be watched for this possibility and an x-ray taken if the possibility suggests itself. The treatment consists in exposure of the dural perforation and its closure, but if suture is impossible properly placed packing can usually be relied upon to conduct the air externally. Infection is one of the greatest dangers in this complication and can often not be avoided.

DEPRESSED FRACTURES: Depressed fractures of the skull if allowed to remain unoperated are a potential danger to the patient, the local irritation produced frequently caus-

ing cortical damage of a permanent nature Therefore all depressed bone should be removed or elevated. Compound communited fractures are best treated by careful debridement, repair of the dura if torn, haemostasis, and loose packing. This does a great deal to prevent infection and frequently permits primary union to occur. It is much wiser to delay any form of surgical treatment until recovery from any immediate shock due to the accident has occurred.

CRANIAL DEFECTS: Defects in the skull from any cause if small cause no discomfort. If large they may give the patient enough annoyance chiefly because of his fear of hurting his brain or for cosmetic reasons to require repair. The best method which should not be undertaken until several months after the wound has completely healed is by the use of a graft taken from another part of the skull consisting of the periosteum and outer table. This removed by a chisel and transplanted into the defect gives good results.

TRAUMATIC HEADACHE At times a head injury causes severe and intractable headache without any intra-cranial pressure being present. The pathology of this is obscure although it has been suggested that the presence of fine arachnoid adhesions is the cause tain of these cases are markedly benefited by the spinal insufflation of air (encephalog-To perform this the patient is placed in a sitting position and 100 or more c.c. of spinal fluid removed 10 cc. at a time and replaced by an equal or slightly less quantity of air, keeping the spinal fluid pressure at a constant level throughout. The procedure is with out danger and its relief may be explainable by the hubbles of air breaking up the adhesions in the subarachnoid space.

TRAUMA TO SPINAL CORD. Fracture of the spine with mjury to the spinal cord is a very serious accident. If actual displacement has occurred and the cord crushed no treatment can have any effect because the immediate result of such an injury is complete and permanent Paralysis A spinal cord once cut will never regenerate. In other cases the paralysis will be found to be partial or late in showing itself. The cause of the paralysis in such cases may be oedema or hemorrhage either in the substance of the cord or between the cord and the dura, or a spicule of a fracture lamina may he impinging on it. Here surgical treatment must be considered. If spinal puncture shows obstruction to the spinal fluid flow immediate lammeetomy is indicated, but when there is no obstruction and the paralysis remains unchanged or improves expectant treatment is the only rational course to follow. In certain

Traumatic pneumo ephalus four days after fracture through right frantal sinus

instances some months after an injury slowly progressive spastic paralysis may appear. This is due to scar production or to cystic collections of fluid in the arachnoid Surgical treatment in these instances often gives excellent results.

TRIGEMINAL NEURALGIA: Neuralgia of the fifth nerve is an exceedingly painful disease rather well limited to the fifth, sixth, and seventh decades of life. It generally involves the cheek or lower jaw, i.e., maxillary or mandibular branches and is almost always confined to one side only. The first branch is sometimes effected when the term supra-orbital neuralgia may be applied to it as it is usually limited to that branch. The pain in any location is sharp and lancinating in character and is brought on by eating, swallowing, talking, touching the face, or cold air. There is no pain between the attacks and none when the patient is quiet as when in bed. The treatment consists in interrupting the nerve connection be tween the sensitive portion of the face and the brain, i.e., by rendering it anaesthetic may be done by the injection of alcohol into the corresponding nerve trunk, preferably at its point of exit from the skull The anaes thesia resulting lasts for a number of months and gives pain rehef lasting on an average for from one to three years. Injections may be re-peated as needed, but the duration of relief decreases after each repetition until they finally

noid spaces which may permanently upset the spinal fluid circulation.

Decompression. In a very occasional case is subtemporal decompressions indicated. Only in those cases where intracranial pressure remains elevated in spite of the above treatment, It is never wise to operate for the relief of intracranial pressure until dehydration treatment has been given a thorough trial. Following this rule will eliminate utterly useless operations in hopeless terminal stages of intracranial injury. No case which can not be controlled at all by dehydration can be saved by surgery, and one cannot help but have the feeling that operating because there is nothing else to do accomplishes nothing more than to discredit surgery.

EXTRA-DURAL HEMORRHAGE: Intracranial pressure may be raised by intracranial bleeding alone. If this bleeding is massive and inside the dura death occurs at once without the possibility of surgical intervention. If it is outside the dura recovery will occur if surgery is resorted to immediately. This being the only complication following head injury in which delay in operative interference is not preferable to haste. The condition of extradural clot is usually caused by a fracture through the middle fossa tearing a branch of the middle meningeal artery, and may follow a seemingly trivial injury. The following characteristic symptoms are observed. After the accident there is a lucid interval of a few hours during which examination of the patient reveals nothing abnormal. Then the patient becomes rather rapidly drowsy and unconscious. there is marked slowing of the pulse and weakness with exaggerated reflexes and a Babinski sign on the side of the body opposite to the clot. In the terminal stage convulsions occur on that side. The operation of choice for removal of the clot is a bone flap turned down to expose the clot. This is preferable to a subtemporal decompression through which the bleeding point cannot always be found. presence of the clot between the skull and the dura makes a flap operation easier than usual because the dura is pushed away from the bone and does not have to be avoided as carefully as is customarily the case.

SUB-DURAL HAEMATOMA: Bleeding within the dura if arterial is almost immediately fatal. If venous it is either absorbed or a clot formed. The symptoms differ from those of extra-dural bleeding most markedly in that the lucid interval may be from a few weeks to several months in duration. The clot commonly known as sub-dural haematoma lies over one side or other of the brain, its characteristic symptom is intractable headache gradually followed by pe-

riods of drowsiness continuing to unconscious-There is a very slight weakness of the side of the body opposite to the clot and a Babinski sign on that side, but convulsions seldom occur. There is usually some congestion of the fundi without definite choked disc being present. The spinal fluid is customarily and paradoxically under normal pressure with a -slight increase in the cell count. - The clot is sharply outlined and of a dark greenish color. Its treatment is surgical and its approach varies with the age of the clot. If it is of short duration it will be found to be firm and must be removed entire through a bone flap. When it is older it will be softened in the center and its cure can be effected by the simple evacuation of the fluid center of the clot through a small burr hole. Once removed or evacuated the bleeding does not recur. These cases are not uncommon but are rarely diagnosed before The chief reason for this is that the trauma is remote and frequently forgotten or not mentioned. This is unfortunate because few surgical diseases make a more rapid and complete recovery than a properly handled sub-dural

PNEUMATOCELE: Aside from the presence of a blood clot within the cranium, intracranial pressure may be raised by the presence of air. It sometimes happens that in fracture through the anterior fossa the dura and skull are injured in such a way that air can enter the sub-dural space from the frontal or ethmoid sinuses. If the air can readily escape again the situation is only manifest by the discharge of spinal fluid from the nose. However, if the dura is so torn that it acts as a flap valve, the air which enters cannot escape. Coughing, sneezing, or blowing the nose forces air in faster than it can be absorbed. The pocket of air thus formed compresses the frontal lobe (See Figure 1) and produces a cyst like cavity which finally ruptures into the ventricle. great part of the spinal fluid may be replaced by the air before death ensues. Clinically the symptoms are a discharge of spinal fluid from the nose followed in a few days by headache and drowsiness. Any fracture involving a sinus should be watched for this possibility and an x-ray taken if the possibility suggests itself. The treatment consists in exposure of the dural perforation and its closure, but if suture is impossible properly placed packing can usually be relied upon to conduct the air externally. Infection is one of the greatest dangers in this complication and can often not be avoided.

DEPRESSED FRACTURES: Depressed fractures of the skull if allowed to remain unoperated are a potential danger to the patient. the local irritation produced frequently caus-

when the total mass of muscle which goes into spasm is reduced by paralyzing part of it as above the intensity and frequency of the spasm is decreased. Further the drooping lower lid found in the usual facial paralysis is not observed because the innervation of the muscles of the upper lip is preserved holding the lower lid in its approximate normal position.

CEREBRAL LUES: Choked disc with headache and high intra-cranial pressure is a not uncommon occurrance in cerebral syphilis. There is great danger of this producing optic atrophy before anti-leutic treatment can sufficiently lower the pressure. The artificial lowering of intra-cranial pressure by sub-temporal decompression will do a great deal to prevent this accident. In the crises of tabes root resection or chordotomy may be of great value.

SYMPATHETIC NERVOUS SYSTEM: Within the past three or four years the sympathetic nervous system has come to be of surgical importance. Sympathectomy was first undertaken for the relief of spastic paralysis, but the results have not proved satisfactory in this condition. It has however been found to be of marked benefit in painful arterial spasm such as is present in Renaud's Disease and an gina pectoris. In Renaud's Disease removal of the lumbar and sympathetic chains markedly improves the circulation of the corresponding extremity and prevents the painful symptoms of the disease. In angina surgical removal or more safely and preferably alcoholic injection of the left cervical chain in a large percentage of cases favorably modifies the attacks. It is necessary to destroy not only the cervical ganglia but also the first and second thoracic ganglia in order to interrupt all the necessary

SPINA BIFIDA: This very common anomaly present at birth is generally outwardly manifest by the presence of a sac protruding from the back in the mid line. It may occur at any point from the sacrum to the occiput and similar sacs are not infrequently found arising from the cranial suture lines. There may be no sac at all only the absence of one or more

laminae being present. This known as spina bifida occulta is only of surgical importance in a very rare instance later in life when progressive paralyses requiring its exploration for adhesions or other abnormality. When a sac is present it may contain spinal fluid alone or any portion of the spinal cord or roots, which latter are always more or less abnormal and deficient in function. The surgical treatment is simple and consists in amoutating the sac and closing the defect the simplest way possible with the least possible tension. There is little surgical risk and no infant who has a spina bifida containing only spinal fluid and without paralysis should be denied the opportunity to grow up to be a normal adult. We feel on the other hand that all cases which have nervous tissue in the sac cannot be expected to grow to be normal individuals and should be refused operation. All cases with paralysis of the legs are included and any case which does not have a normal sphincter reflex should be regarded as a questionable subject for operation and the family warned of the possible paralysis, trophic ulcers and incontinance which may persist as long as the child lives. Some knowledge of the contents of the sac can be gathered from its shape, simple meningoceles being as a rule pedunculated with but one spinal lamina absent. Large defects and sessile sacs contain nerve tissue most frequently. The best time for operation in the new born baby depends on the condition of the skin over the sac. It it is thin and shows signs of breaking down operation should be performed as soon as possible. If the skin is thick and of normal appearance it may be delayed till the child is older.

#### CONCLUSIONS

A brief discussion of a few neurosurgical conditions other than neoplasms and infections has been attempted.

Certain of these diseases which have generally been considered as hopeless can be treated satisfactorily by neurosurgical methods.

No detailed description of pathology or technique has been included.

# CLASSIFICATION OF ENDOCARDITIS\* By WILLIAM F. JACOBS, M.D., BUFFALO, N. Y.

U NIFORMITY of nomenclature for classification of disease has been a problem for many years. The need for standardization is urgent.

What is true concerning general disease con-

\*Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y., June 6, 1929

ditions is equally true pertaining to cardiac disease.

When we consider the innumerable terms that have found application to the variety of heart conditions, the desirability for uniformity immediately becomes apparent.

The nomenclature, terminology and group-

ing of endocarditis by clinician and pathologist would at times, appear to be at a variance. This is in part due to the fact that they do not always speak the same language, and also because of their different viewpoints.

Changing conditions in methods of practice, the multiplication of laboratory aides, much more comprehensive studies, are in our day responsible for a greater degree of accuracy

and completeness in diagnosis.

The relation of clinician and pathologist too. has been changing, they have become more intimate, often meeting on common ground, it being not unusual for the pathologist to forsake his lair and visit the bedside with the clinician and the latter more frequently is found attending the post-mortem table. Many more autopsis are being made. An "esprit de corp" is developing, a cooperative spirit, that should work out finally not only to a better common understanding, but also, let us hope. to the use of common terms and language.

The heart committee of the New York State Tuberculosis Association with the approval of the American Heart Association, have published a brochure on "Criteria for Nomenclature, Diagnosis and Classification of Heart Diseases," from the press of Paul Hoeber. This little booklet I heartily commend to you all. It is a product of careful study and represents the conjoined effort of representative clinicians, pathologists, anatomists and physiologists.

It is intended primarily as a guide to the final classification of all cardiac conditions, so that part of it concerned with endocarditis involves our special interest. (See Table 1).

At the Buffalo City Hospital we have followed the Bellevue nomenclature for over ten years. Six months ago, a committee of which I have been a member, began weekly meetings to consider and pass on the discharge, death and post-mortem diagnoses, with a view of developing a uniformity so that filing by the registrar would be facilitated. Naturally, we encountered much to be remedied, but the effort is proving worthwhile and it is admitted that the records are in much better order.

We have added to the Bellevue nomenclature in many instances, and are looking forward to the revised issue which we hear is, in

contemplation.

On the subject "Heart," we decided to follow the lines laid down by the Heart Committee and American Heart Association, and had the tables mimeographed for the convenience of the House Staff and students.

Before going any further, let us briefly consider endocarditis. First, its limitations. Many of us are inclined ordinarily to limit endocarditis to the reflections of the endocardium over the valve leaflets, when as a matter of fact, it includes the mural surfaces, papillary muscles and chordae tendinae.

Clinically and pathologically, acute and chronic forms are recognized, and the clinicians have compelled the recognition of a third—the

sub-acute.

Under the acute type, the clinician speaks of septic, malignant, ulcerative, and septico-pyemic. Under the subacute, the terms benign and simple, and sub-acute bacterial endocarditis are spoken of.

In chronic cardio-valvular disease with the scarring deformity, the clinician generally speaks of the particular valve lesion, that is, functional lesion, regurgitation, insufficiency or stenosis of either the mitral, aortic, tricuspic or pulmonic valves. The pathologist makes use of such terms as mycotic, polypoid, ulcerating, vegetative, verrucous for the acute endocarditis; for the sub-acute, verrucous and simple. The chronic valve defects are for the

pathologist a chronic endocarditis with the in sufficiency or obstruction as noted clinically

Both chincian and pathologist recognize the rheumitic fever type of endocarditis and also the choreic, which the pathologist characterizes as simple or vertucous, meaning wartlike Both also speak of the recurring type that lights up with a renewal of joint symptoms, fever and pain and pathologically with thrombotic deposits and an active inflammatory reaction in the involved endocardium. Carefully analyzed, it would appear that there are no real differences excepting in terms.

The life history of infections has taught us that endocarditis is always secondary to sistemic my asion by disease prolucing bacteria these having gained entrance thru some local ized focus of infection. The nature of this particular germ of bacterium as to degree of virulence determines the nature of the inflammatory reaction in the heart. This ranges from the simple warflike excrescences along the edges of the mitral leaflets as in rheumatism and chorea, to the more vegetative, cauliflower-like and ulcerative type with embolic phenomena as found in profound septic conditions that lead to a rapidly fatal issue.

Subacute bacterial endocarditis being an intermediate form caused by the streptococcus Venidans the vegetations are a little more fleshy like, not so hard as in the rheumatic and chorece types. They also exhibit a tendency to spread upward on the mural endocardium down along the Chordae Tendinae and papillary muscle. Also along the under surface of the vilve leaflets following the direction of the blood stream the mural endocardium under the aortic cusps and up onto these valves also.

Because of the longer course as compared to the acutely septic types this is called 'sub-acute' but it also finally leads to a fatal issue

In both acute septic and subreute types we have every reason to believe that they are superimposed on previously damaged valvular endocardium, that of course, presupposes a previous acute endocarditis that may not have registered clinically but that did leave thickened damaged valves which furnish an ideal area of lowered resistance. The nature of the germ may be that of the recurring type or a more virulent germ factor may come into play, with course and outcome accordingiv

Finally, in the chronic deforming types the acute stages may have never registered chinically, its development having been insidious, so it is discovered after cardiac disability presents or incidentally at the time of examination for insurance. Or it may be perfectly clear that the condition goes back to repeated tonsillar infections with or without rheumatic joint symptoms. So that the heart with the chronic

scarring deformity depending on form and valve, may serve an allotted spin of life without a new superimposed infection

Without attempting a detailed description of the pathology in endocarditis and going into the clinical course, let us rather briefly take the criteria developed and clissify them

## (15) Endocarditis

(a) Acute (b) Chronic

The acute is obviously always a sequel or a part of a general or local discase. The table under (A) Ptiological, lists a series of causes grouped as to kind and numbered from one to four. The first 'Unknown should only be used after all available methods have failed.

The second group is capped by 'Rheumatic Feer,' this with (a) polyarthritis, (b) chorea (c) growing pains (d) tonsillitis, (e) pharvingitis (f) purpura, erythema nodosum covers a definite type of infection that is well under stead

stood

The third Syphilis" while varied in its manifestation attacking any and every kind of tissue, the heart valves and vessels have always had a peculiar affinity for this. The aortis with aortic endocarditis, therefore deserves special consideration as a definite etiologic factor in a group by itself.

In the fourth Bacterial Infection," the name of the bacterium should always be specified if possible. This means blood culture. It is well to remember in this connection that there are very few of our pathogenic organisms that have not been found to be the cause of endocarditis. The subacute should have streptococus Veridans added

One further observation should be made in the instances 2-3-4 and that perfains to the activity of the process. Is it still active or no longer active? This should be stated.

(16) Cardio Valvular Disease

These valve defects, such as with insufficiency and stenosis should always be preceded by (15) being a sub division of chronic endocarditis. They are essentially a chronic inflammatory process and should therefore be regarded as in continuous activity, whether involving the valves only or extending to mural endocardium, papillary muscle and chordae tendinae.

It will be noted that in this simple and brief classification, none of the many descriptive terms appear as to the character of the vegetations or course of the disease.

These, of course, have a place in the clinical record and the protocol of anatomical findings

We offer that this simple method and classiheation that considers the etiological anatomical, and physiological is not alone practicable but very desirable

# PRESENT CONCEPTIONS AS TO THE CURABILITY OF SYPHILIS—METHODS OF TREATMENT\*

# By HAROLD N. COLE, M.D., CLEVELAND, OHIO

From the Department of Dermatology and Syphilology of the Western Reserve University School of Medicine, Cleveland, O.

ONSIDER for a moment how many different drugs, how many different modes have been employed at one time or another in the treatment of syphilis. instance, among my books is a first edition, 1519, from Fournier's library, of Ulrich von Hutten's book, "De Guaiaci Medicine et Morbo Gallico." The author, von Hutten. was a sufferer from that apparently new disease in his time, syphilis. He was cured, ostensibly, by the use of guaiac, and also cured several of his friends. He felt so strongly on the virtues of the medicine that he wrote a book on the subject that is quoted, even to this day. History tells us that Benvenuto Cellini treated and cured himself with guaiac at a time when the physicians wished to treat him with mercury.

Since the earliest history, ointments of this metal had been employed by Arabians and others in the treatment of skin diseases. How natural, then, it must have been to try its effect in that disease which was spreading so rapidly throughout Europe around the beginning of the sixteenth century. It was first used in the form of inunctions, or rubs. Bethencourt suggested starting a course of treatment with one rub a day, gradually working up to even three rubs in twenty-four hours, depending on the severity of the disease, the constitution of the individual, and the way in which he developed a salivation. Among the old syphilographers, salivation was the acme and desired end of all mercurial treatment, and the patient who was not excreting a quart or two of saliva in twenty-four hours was not getting the proper mercurial effect. Almenar<sup>1</sup> alone, among the physicians, as long ago as 1502, was against the vogue of profuse salivation. He purged the patient, used blood letting, cathartics, gave a mild diet, and rubbed in up to one-half of an ounce of the ointment three times in three to five days, and continued it if there was no salivation up to the tenth day. Contrast this with Sydenham's recommendation of three ounces of ointment in three successive days. Following the use of mercury in an ointment made up of various complicated bases we next find it suggested by Pietro Andres Mathioli2 that it be used internally in the form of the red precipitate. Later it was employed in various types of pills, in fumigations, and in solution, for example from

\*Read at the Annual Meeting of the Medical Society of the State of New York, at Albany, N. Y., May 22, 1928.

the Vienna school of medicine as van Swieten's sublimate solution.

However, mercury was by no means the only remedy used in olden times. Many doctors discouraged the use of this drug and why not, when one reads of the heroic treatments the patient was forced to endure? In fact the average syphilitic made his will before undergoing his "Careme de Penitence," as Bethencourt Zittman's decoction attained an terms it. enormous popularity in the eighteenth century; for a time opium was used extensively; to say nothing of decoctions of holy woods (Ligni Sancti) from the Orient; sassafras; sarsaparilla; oranges; lemons, bitter sweet and so forth. Sooner or later, however, the old time physician was forced to turn to mercury, and it remained for the great French syphilographer Phillipe-Ricord<sup>2</sup> at the middle of the last century to first put the treatment of syphilis on a rational basis. He advised the proto-iodide tablets by mouth, using smaller doses, and endeavoring to discourage the severe therapy. His patients, at signs of intolerance, were put on smaller doses. The treatment was continued for six months and then followed by potassium iodide. He was probably among the first of the physicians to treat the patient and not the syphilis alone. Later, one of Ricord's most famous pupils, Alfred Fournier, suggested the use of the so-called intermittent treatment. The relative merits of the continuous versus the intermittent type of treament will be discussed later.

In 1905 Schaudinn discovered the spirochete, or treponema pallida, and shortly thereafter Paul Ehrlich made his remarkable syntheses of the arsphenamines. In almost the same period of time Wassermann also brought out his serological discoveries. These events all taken together have exercised a profound influence, not only on the diagnosis, but on the course and treatment of syphilis. Metchnikoff and Levaditi in the laboratory, and Neisser in the jungles of Java, had already presaged the coming event. Even poor old John Hunter, when he inoculated himself with the pus from a purulent gonorrrhœa and contracted lues as well had shown that syphilis was an inoculable disease. This was repeatedly verified, thereafter. It is said that Ricord, alone, in his fight to overcome Hunter's mistaken belief in the oneness of gonorrhæa and lues, inoculated many hundreds of people. Yet by the actual discovery of the germ of syphilis, and by Wassermann's serological work we, for the first time, had something tangible on which to base our diagnosis and on which to follow out our therapeutic procedures. Even the writer can remember the time when we were forced to await the secondary eruption before beginning antiluctic therapy. How otherwise could we properly distinguish between certain chancroidal and primary lesions? Moreover, Levaditi and Sazerac in 1920, following up Balzer's suggestion as to bismuth, have added another valuable drug to our antiluctic armamentarium

Moreover, certain laboratory studies have enabled us better to understand the spread of syphilis through the body, and to relate these to better treatment of this condition, we refer to certain immune reactions The writer, likewise, remembers the time when it was advised to excise the primary seat of invasion. It was felt that the organisms developed only very slowly at the point of inoculation, and that only after an appreciable length of time were there enough of them locally to set up the local sore the chancre This focus should be Thanks to the studies of Brown and Pearce and to Kolle and those of many other workers, we now know that syphilis is generalized very soon after the inoculation Kolle and Evers have recently shown in rabbits that the infection spreads from the point of inoculation to the inguinal glands within thirty min-Within five minutes after treponema have been introduced into the scarified skin these workers have found infections of the lymph glands six centimeters from the site of the abrasion and inoculation Does this change our conceptions as to the types of treatment advisable in a case of syphilis? Possibly a few quotations from different studies on immune reaction in this disease can assist us to answer this question

Metchikoff and Roux, Neisser and others working with apest found that luctic animals could be reinfected with syphilis if the sec ond moculation was made comparatively soon after the first They could not be reinfected if it was tried after the first infection was well developed. This has been found true with rabbit syphilis and is probably true with man Neisser taught that if he was unable to remoculate an age with syphilis it was because the animal already had a well developed disease but that if he was successful there was no lues present. In other words he felt that there was no immunity to syphilis without infection. He thought that as soon as the ape was cured that he could contract lues again Chesney and Kemp have found that an immunity may develop under some conditions, in rabbits, and perhaps even after rection has been eliminated

The French schools would d

state of syphilis into two distinct stages-a first phase in which the chancre is automoculable and the sero-reaction negative the second period the chancre is no longer auto moculable, and the sero-reaction becomes The sero reaction does not neces sarily start exactly at the time when the in oculability disappears, in twelve days, but it is usually between the thirteenth and thirtieth They held that this so called prehumoral period holds the most chances of definite sterilization of the disease This brings up the question of so called superinfection, reinfections, and pseudoinfections Neisser thought that it was impossible to reinfect a man who already had a syphilis. It was considered doubtful for many years, and probably is true under most conditions However, Hashimoton has recently superinfected twenty proven hu man syphilities in various stages of their syph ilis, injection of the material having been made into the flexor surfaces of the arm. Injections were all controlled Infiltration ulcers and no dules later developed, and treponema were demonstrated locally in eighteen of them Chesney and Kemp, Brown and Pearce, Frei and others have found the same thing true in It has been found in rabbits that if they have an early moculation syphilis of the testicle that if they be inoculated into the other testicle they can be superinfected. It is ensier to achieve this superinfection if a different ctrain of trenonema be used. On the other hand Chesney and Kemp have found that if they take a syphilitic rabbit abrade an area on the dorsum of the back producing a crust, and then remove this crust and rub an emulsion of spirochetes into this area that they can superinfect this rabbit already syphilized. In other words, superinfection is a possibility onoff<sup>8</sup> has recently reported a superinfection in a tertiary luctic Bernard<sup>9</sup> thinks superinfection is possible in the primary stage up to the thirty-first day of the chancre, but especially in the first cleven days. He thinks it would be an exception in the secondary stage, but pos sible in the tertiary stage

Pseudo infection is nothing but a manifestation of the patient's own syphilitic invasion Chancre redux is a pseudo infection is endogenous in origin indicates insufficient treatment, and may be, possibly, secondary in part to trauma

The question of reinfection comes up We have been reading so much in the literature to day of reinfection in lies even of second reinfection. It is true that before the days of arsphenamin reinfection was rarely mentioned. We are now seeing so many reports of reinfection that there must be some truth in them. Moreover, as Chesney points out, so

many of them are in individuals who have been diagnosed early and treated thoroughly with arsenic and other heavy metals. Nevertheless, in the light of studies made on the ape, on the rabbit and now in humans, by Hashimoto, we probably should accept these reports conservatively. Certainly many reinfections could be superinfections; at least there is that possibility.

We simply mention these different laboratory studies inasmuch as they naturally lead us to a better conception of syphilis as considered from the treatment standpoint. so-called prehumoral stage of the French is also to be termed the sero-negative primary. After the serology is positive on the primary we speak of the sero-positive primary; and finally of the secondary, latent and tertiary stages. The sero-positive primary and the secondary stages are closely related. Despite the rapid spread of the treponema after invasion, the earlier the diagnosis the better the prognosis. The earliest type of treatment in use today is the so-called prophylactic treatment. After all, this is given on the supposition of an infection and should be considered from this standpoint. Naturally the earlier the prophylaxis the better the result. Despite some recent reports to the contrary, early thorough prophylaxis within a few hours of the exposure, using plenty of soap and water, elbow grease and thirty per cent calomel ointment rubbed in for five minutes by the clock, will prevent many a case of later syphilis.

Once the disease has been contracted what are the approved remedies to be used in eradicating its cause? Certainly potassium iodide should be considered. Pearce<sup>11</sup> has found in experimental rabbit syphilis that its use definitely changed the severity of the acute infection and diminished the period of the experi-

mental disease.

## MERCURY

Despite the present tendency to neglect mercury in favor of bismuth, we believe that physicians should not forget its value. We can remember several instances of patients susceptible to the arsphenamins and not reacting to bismuth therapy, who responded nicely to hydrargyrum. It is true that it is more nephrotrophic than bismuth or arsenic, yet it is not so prone to cause liver damage or skin reaction. For quick mercury action we may employ soluble daily intramuscular injections of the biniodide or binbromide, or the cyanid or of flumerin. Among the semi-soluble mercury preparations we are still using the mercury salicylate in doses of 0.1 once a week. We think there has been too great a tendency to discredit this valuable drug. Mercury inunctions are still of great service in a continued plan of

treatment, where gradual mercury absorption and excretion is desired. The clean inunctions, where the extraneous mercury is removed from the skin after thirty minutes rubbing, are probably as potent as where the ointment is left after the inunctions. Moreover in a scheme of treatment involving continuous therapy such as is now widely employed, it is well to have, not two, but three different preparations which may be alternated.

# BISMUTH

Bismuth is a drug that has only come into use since about 1920. It apparently has a stronger parasiticide action than mercury and it does not seem to be so toxic in its action on the kidneys as the latter drug. Nevertheless we are now reading of some cases of poisoning from this remedy and it is not to be used without care. Herzog12 says that bismuth preparations to be effective should have at least six centigrams of metallic bismuth in a dose and that in six to seven weeks the patient should receive around 1.5 gm, of metallic bismuth. This, of course, eliminates intravenous therapy in the use of this remedy, inasmuch as by this route it is possible to use no more than four centigrams at a dose and serious symptoms may arise from three centigrams. Moreover, intravenous therapy with this drug is ten times more toxic than intramuscular therapy. muth is probably a remedy superior to mercury. This, however, will require many years of observation before we can fully substantiate it. It seems to be quite active in changing the Wassermann reaction, and is of high therapeutic efficiency.

There are many different bismuth preparations on the market, for example the bismuth salicylate and the potassium-bismuth-tartrate, are very popular in this country, while in Germany tartroquiniobine is widely used. In both France and England a finely divided preparation of bismuth suspended in oil is in general use. It will require much time and study before the most suitable bismuth preparations can be worked out from the clinical, bacteriological and pharmacological standpoints.

# ARSENIC

Arsenic in the form of arsphenamin is, after all, the most potent remedy that we have today for treating syphilis. Its action is essentially that of a spirillicide. It is more tonic than the mercury or even the bismuth. Moreover, it does not have the depressant action that we see with mercury, nor is it quite as depressing as bismuth, though bismuth, in this quality, is not as severe in its action on the human body as is mercury.

Arsenic is more toxic in its action on the

liver and on the skin, and patients who are under therapy with the arsphenamins should be carefully examined at each visit from the standpoint of irritation of the kidneys, possible icterus, and certainly from the standpoint of irritation of the skin. It is not sufficient simply to ask the patients whether they have noticed any skin eruption, but before each injection of one of the arsphenamins the patient should be stripped and examined for evidence of urticaria, of erythema, or even of a mild pruritus Care in this particular may often be the means of preventing a severe dermatitis exfoliativa We have seen many patients who have gone to a physician and received another injection of arsphenamin when they already had an arsenical eruption on the skin The result, natu-The old arsphenamin is rally, was disastrous probably the most potent one of this group, and generally can be employed in doses of from 02 up to 04 gm depending on the age of the individual, the sex and their size believe that the tendency today is not to use quite so large doses. This is certainly true in Europe In fact, in Europe, generally, neoarsphenamin is the drug of choice, and is used in doses of 03 up to 075 gm. It is rare for the German syphilographer to use a larger dose than 06 gm and we are inclined to agree with them in this particular There are some cases where the sulpharsphenamin is of use, particularly where it is necessary to give the drug by intramuscular injection However, it is a treacherous drug, one that is liable to set up a very severe hemorrhagic reaction with little or no notice and we believe that it is being used less and less on this account

The final arsenical to be recommended is This preparation, brought out tryparsamide by the Rockefeller Institute, is widely used in the treatment of central nervous system syph-It is especially employed after malaria therapy and is of great value. In using it we must watch the optic nerves very closely, having preliminary perimeter, including color, examinations It is contraindicated with contracted fields Occasionally the patient will complain of a little blurring after one or two injections which clears up if therapy is stop-In a few weeks it can be renewed and usually continued with no further trouble We often give as much as fifty weekly injections, starting with doses of 10 gm and working up to 30 gm

# INTERMITTENT VERSUS CONTINUOUS TREATMENT FOR SYPHILIS

Now having considered the individual remedies for our arminentinum—how should they be used? As we have already mentioned, Ricord advised continuous treatment therapy,

and advised its being carried on for around a Mercury was used the first six months and potassium iodide later. His greatest pupil Fournier, was the means of the introduction of the intermittent treatment which has been so popular for the last fifty years Once more we find a tendency for the syphilographers to veer back to the continuous form of treatment We believe this to be with reason Almkvist18, in Europe, seems to have been the first one to take up this method of treatment. In our country Moore and Keidel14 have been carry ing it on for some time. They reason well "that a few patients with a primary or possibly a secondary syphilis may be biologically cured from a single course of arsphenamin treatment In most instances, however, this is not pos sible, and virulent organisms are left in various foci in the body. In the days before arsphen amin therapy the patient probably built up a certain amount of resistance or immunity, if you wish to call it such, on his own part against the disease Since we are using ars phenamin, however, little or no opportunity for bodily resistance to be built up has been given and the patient may enter this period following a course of arsphenamin therapy with little or no resistance against the living organisms in the tissue. The result may be that the organisms once more begin to multiply and disseminate themselves, resulting sooner or later in a delayed or recurrent type of the disease" If, however, continuous treatment is used, that is, courses of arsphenamin followed by courses of mercury, or of bismuth, this is not possible The patient may be kept under continuous therapy, first with arsphenamin, for example, then say with bismuth perhaps later with more arsphenamin, for example, then again with mercury and so on for such a period of time as completely to cure the patient and allow the organisms no chance to develop

It is to be noted that Colonel Harrison in his recent publication on Wassermann Treatment of Syphilis in England his come to the conclusion that his patients do better with interrupted courses of treatment. Nevertheless, we personally believe the continuous therapy to be the rational mode of treating syphilis and would advocate its adoption by every thoughtful physician.

## ABORTIVE TREATMENT

What then should be the treatment of choice in the early syphilitie in the light of our continuous therapy and from the standpoint and viewpoint of different syphilographers? Let us first consider the so called sero-negative primary, the type of case in which the abortive treatment is recommended.

The abortive treatment is all right, provided it

be thorough enough and provided the diagnosis be made early enough. It should be applied to sero-negative primaries and even then the patient should be followed in his after life like the ordinary syphilitic. Gougerot and Fernet<sup>15</sup> advise for such cases a course of intense neorsphenamin treatment, up to a total of six or seven grams, a rest for several weeks and then a repetition of this treatment, followed by treatment with mercury and bismuth for six months. Bernard<sup>16</sup> likewise insists on a long, intensive, abortive treatment with clinical observations thereafter.

The late Dr. Fordyce<sup>17</sup> suggested for patients in this stage, where we hope to abort the disease, that there should be at least two courses of eight doses each of arsphenamin and two courses of fifteen injections each of mercury. He emphasized the need of continuous observation and control of Wassermanns, in even these cases. Cannon<sup>18</sup> recommends as a minimum standard of treatment at least thirty injections of arsphenamin, or its equivalent in neoarsphenamin, and forty-five injections of mercury salicylate, over a period of nine to ten months.

Hoffmann of Bonn feels that an early case of this type can often be cured by a course of arsphenamin followed by a course of bismuth. Almkvist would use in a case of this kind in addition to the arsphenamin course ten injections of bismuth and then ten injections of For example, he would use the mercury. Spirobismol and the mercury salicylate. Schamberg recommends his course of arsphenamin be given as follows: 0.9 gm. of neoarsphenamin twice a week for two weeks and then once a week in a case of this type. Stokes recommends three almost maximum doses in the first nine days of the disease and then would follow this weekly with milder doses, after which he would administer mercury. Both of these types of administering arsphenamin are given, of course, with the idea of sterilizing the lues. Keidel and Moore<sup>14</sup> in their outline for continuous therapy recommend eight injections of arsphenamin in the first series, while subsequent courses of injections would consist of six. In order to utilize the effect of the arsenic as much as possible the first mercury course between the courses of arsphenamin should be four weeks, gradually lengthened to six, eight and ten weeks in respective subsequent courses. As long as nine years ago they set up a standard of one year's continuous treatment after the blood Wassermann and spinal fluid had become and remained strictly negative. The patient is then put on a full year of probation during which he receives no treatment, and if in this time he develops no lesions of syphilis, the blood Was-

sermann tested at frequent intervals remains negative, physical examination and punctures are likewise negative, the patient is allowed to marry on the supposition that he is probably cured.

Tadassohn.19 The German syphilographer, writing on the treatment of syphilis emphasizes the need of early diagnosis. He still advises the use of combinations of therapy, that is of arsphenamin, mercury and bismuth. He still thinks that arsphenamin is the specific treatment of syphilis, and mentions the large number of reinfections that are being reported since its use. He thinks that the use of too little arsphenamin is bound to predispose to the central nervous system recurrences. his sero-negative primary cases his treatment during the first course would run somewhat as follows: on the first day, neoarsphenamin, 0.3 gm., second day an injection of Spirobismol (tartroquiniobine), 1.5 cc. to 2 cc., that is, metallic bismuth 6 centigrams, or of mercury salicylate, 0.1 gm; the sixth day neoarsphenamin 0.45 gm.; the ninth day the same injection of Spirobismol or of mercury; the tenth day neoarsphenamin 0.45 gm. After this he would give his neoarsphenamin injections about once in five days up to a total of 5 gm. to 5.1 gm. and interspersed along with this Spirobismol, 35 cc to 40 cc, that is 1 gm. to 1.2 gm. of metallic bismuth; or twelve to fifteen injections of the mercury salicylate. In the sero-negative primary cases after a rest of four to eight weeks he would give another cure of like length. This would constitute the treatment of a socalled abortive case.

With a sero-positive or a secondary eruption he would give three of these cures and after three to four months a fourth cure. During the first cure Jadassohn would advise a Wassermann along with the first, fifth, and sixth injections, and two and four weeks after the first cure. He also advises serological tests at the beginning of the second cure. and at the time of the second neoarsphenamin of the second cure, also at the end of the second cure, and every four to six weeks the first six months, every eight to twelve weeks the second six months and the second year every three months. At the end of the second year he would advise a lumbar puncture, and at the end of the first and second years 0.45 gm. of neoarsphenamin and a blood Wassermann one and five days afterwards. The patient is then discharged, but a Wassermann advised every year.

As we drift from the sero-negative primary into the sero-positive primary we find that our treatment is much the same with the different syphilographers. For example, Almkvist would recommend instead of his abortive treatment

of ten injections of arsphenamin, ten of bismuth and ten of mercury, that the same course of treatment be repeated, treatment continuing for seven months. If he has a secondary eruption he would recommend an even longer course of three courses of treatment, or arsphenamin, bismuth and mercury, duration ten and a half months, or in a more resistant case even four of these courses, duration fourteen months. If we examine the recommendations of these different syphilographers, combine them and attempt to evaluate them we find several deductions that are to be drawn. In the first place, all the men emphasize the necessity of making a diagnosis as early as possible. We should not wait for a seroreaction to become positive. Diagnosis should be made by means of a darkfield, or if not by means of the darkfield, by the use of gland punctures, saving many valuable days in instituting treatment. Too much emphasis cannot be laid on this point. A week at the beginning of a syphilis may be of as much value for treatment as a year, four or five years later. It may mean the sterilization of the disease. Hence every suspected case of syphilis should be diagnosed as soon as it is humanly possible, not waiting for the serology to become positive, and it is certainly criminal to wait for a secondary eruption, as we so often see even in this day and age of medicine.

Having made a diagnosis, the treatment should preferably be continuous in type, in the hope that thereby we may actually eradicate the disease from the human system. Throughout the treatment frequent serological examinations should be made. Much depends on the reaction of the blood as to future treatment and as to the amount of treatment necessary. Moreover, we should not neglect frequent physical examinations to determine the course of the patient's condition. It is probably impossible to outline any routine iron-bound chart that could be used on every patient seen. One man will take arsphenamin well. next man will develop a mild nephritis after the use of mercury or of bismuth. Another patient may show an erythematous eruption after the second or the third injection or ars-We repeat that an iron-bound phenamin. chart is only a convenience and cannot be used in every case.

Nevertheless as near as possible we shall submit what we think comes closest to the ideal of present conceptions in the treatment of an early syphilis.\*

# Sero-negative Syphilis

We would give arsphenamin, 03 gm. to 04 gm the first day, or its equivalent in neoarsphenamin, and repeat this the fifth and tenth

day, and then once a week up to a total of ten injections, if the patient stands it well This we would follow immediately with ten weekly injections of one of the above mentioned bismuth preparations. After a second like course of arsphenamin we may put the patient on unguentum hydrargyrum, 4 gm to an inunction, six days a week for a total of fifty inunctions. Along with this therapy we would advise potassium iodide internally With the average sero-negative primary two such course of arsphenamin will suffice Mercury salicylate may be substituted for the inunctions. It might be well to follow the mercury with another short course of bismuth injections. We would advise that a blood Was sermann be taken at the beginning and at the end of each course and the first day and the fifth day after the first injection of the second and third course of arsphenamin. We would advise a lumbar puncture early in the course of treatment and again at the end of the first year. If these are both negative, probably further exploratories of this type will not be necessary.

### Sero-positive Syphilis

With a sero-positive primary eruption early in type, we would certainly advise at least three of these courses of treatment and with a secondary eruption at least four of them. The patient should then be put on a probation period of at least a year, with a blood Wassermann every month or so. If, at the end of this time, complete physical examination and puncture are negative, permission should be given the patient to marry, though they certainly should come in for examination every six to twelve months for the next two or three years and have yearly physical examinations.

Naturally with later cases of syphilis it is rather difficult to carry out any definite routine of treatment. Each case is one unto itself. We would likewise use the heavy metals here along with potassium iodide. Naturally great stress would be put on careful physical examination to discover any possible internal ravages of the disease With syphilis of the central nervous system the same remedies are to be recommended and if physical findings and serological findings do not respond we would unhesitatingly recommended foreign protein, or better, malaria therapy. We are employing malaria therapy more and more and find it to be of the greatest help in coping with stubborn central nervous system lucs. expecially with taboparesis. Our results from

# CHART FOR ANTI-SYPHILITIC THERAPY

Day or Week	Arsphenamin	Віѕмитн	MERCURY	KI	REMARKS
Day 1 5 10 (Week 2) 17 Weeks 3 to 8	0.2 0.3 0.4 0.4 0.4	0 1 to 0.2			Wassermann General physical examination Lumbar puncture Wassermann
Weeks 9 to 18		10 injections 0.1 to 0.2 intra- muscularly	-	0.5 x.i.d. p.c.	Treatment average seronegative primary finished end of 40th week. Seropositive primary end of 62nd week. Secondary 74th to 84th week
Weeks 19 to 29	10 injections each 0.4 total 4.0 or neoarsphenamin 6.0				Wassermann 1st day and 5th day after 1st arsphenamin Wassermann
Weeks 30 to 40			HgSal 0.1 every week total 1.0 or 50 to 80 Hg. inunctions	0.5 x.i.d. p.c.	Wassermann
Weeks 41 to 51	10 injections each 0.4 total 4.0				Wassermann 1st and 2nd day after 1st injection General physical examination Wassermann and lumbar puncture
Weeks 52 to 62		10 injections 0.1 to 0.2 Total 1.0 to 2.0		0.5 x.i.d. p.c.	Treatment seropositive primary completed. End of this course Wassermann
Weeks 63 to 73	10 injections each 0.4 total 4.0				Wassermann
Weeks 74 to 84			HgSal 0.1 every wk. total 1.0 or 50 to 80 mercury inunctions	0.5 x.i.d. p.c.	Treatment average secondary case completed at the end of this course

foreign protein treatment have not been so encouraging.

# Malaria Therapy

Malaria treatment should only be instituted under the most careful hospital supervision. Careful check should be made on blood pressure, blood study and blood chemistry of the patient. We routinely are typing their bloods, inasmuch as in several instances acute collapse has been averted by transfusion. Malaria therapy is not without risk, but where one sees the results in a class of patients otherwise often beyond therapeutic hope it is a great boon. We generally follow up these cases with arsphenamin but especially with tryparsmide intravenously, often giving it over a long period of time.

# General Discussion

What is the answer to present day therapy of syphilis? Is syphilis on the decline or is it on the increase? In 1926 Jadassohn (20) reported the results of a questionnaire sent out to fifty-one specialists in nineteen countries as to their views on the decline of syphilis and its relations to treatment with arsphenamin. In fourteen of these countries there was a unanimity as to the decline of the disease. In Italy six out of the seven replies showed a decline. In France there has been an undoubted decline to the extent of 50% up to 1923, but of recent years Jeanselme had observed a flare-up in Paris which he attributed to immigration of foreign workmen. The decline in Bulgaria, Denmark and Sweden was fourfifths; in England and Switzerland at least one-half; in Holland three-quarters, and in

Italy one-third. Scandinavian countries today have almost no acute syphilis. Almost all of the specialists attributed this decline to the use of arsphenamin. In a recent paper one of our well known American syphilographers, in one of the great medical centers of this country decried the factthatthey were having difficulty in getting enough syphilis material for teaching purposes. While the writer regrets to say that this is not the case thus far in Cleveland, yet he, too, feels that syphilis today is possibly on the decline. Certainly we rarely see the rupoid and malignant types of syphilis that were formerly encountered. We believe that with education of the medical profession and with proper education of the laity as to the consequences of this disease that much good will result. We would doubly emphasize the necessity of early diagnosis and of thorough treatment along with the more general and universal use of prophylaxis. With these forward steps and with compulsory examination of all applicants

for marriage, syphilis in the next twenty-five to fifty years will truly take an enormous decline. Perhaps the day will actually come with syphilis as with typhoid fever that the medical schools will have difficulty in getting material for teaching purposes.

# WHAT MAY THE DOCTOR GAIN BY DISCRETION IN READING? By J. BAYARD CLARK, M.D., F.A.C.S., NEW YORK, N. Y.

O this, the answer is both forthright and clear, for if he already has not made that blessed discovery, he may gain for himself a new heaven and a new earth.

Said Ralph Waldo Emerson: "We love to associate with heroic persons, since our receptivity is unlimited; and, with the great, our thoughts and manners easily become great. We are all wise in capacity, though so few in energy. There needs but one wise man in a company, and all are wise, so rapid is the contagion."

Through reading of the right sort we are brought into the company of the great, into the company of the wise; it is the doorway of a new companionship, the entrance of a new radiance in life. How well Osler, the brightest star in our recent contemporary firmament, knew this. He became the companion of the great men of all time; much of his life was spent in their company—until finally, he too, became one of them. But he did not lose touch with the illuminating souls of his own time because he dwelt so much with those who had gone; rather, he allowed them to complement each other, and from those of the past he learned to measure and evaluate those of the present. We need not dwell on the ennoblement of Osler's character through his knowledge and friendship with the great ones of our profession who went before, because through

his influence this ennoblement is now filtering through the faculties of our own medical schools and to the students of our own time. They are learning to make friends with those large figures of the past in whom our profession is rooted, and by that companionship are gaining a nobility all too little appreciated before Osler's time. This is his bequest to the present, and the future, and it stems from what he gained by reading.

Who of us in our boyhood did not gather into our minds visions of heroic persons and generous deeds? Who of us did not see the possibilities of life lived on a higher plane; a fairer outlook and a better portion for the multitudes submerged in ignorance, in poverty and disease?

In our youth it was with thoughts such as these in our hearts that we turned our stepsthat is, most of us did, I am sure-toward the career of our choice. We could as well have gone into business or, possibly, into some other profession; but there was that, somewhere, down deep in our nature, which turned us toward the profession of medicine Again, I believe, those of us motivated by such thoughts have no regrets concerning our early decision, but in the ebb and flow of life and the changing and varying conditions of society that accompany it, there come times when even the path of one's chosen career becomes

thorny and strewn with obstructions. With the traditions of our calling still warming our blood, we press on amidst increasing difficulties and into a future befogged by we know not what.

With the rapidly expanding knowledge within the precincts of our own profession we are often put to it to keep acquaintance with what is growing up about us, let alone looking across the boundary and studying the activities of those just beyond.

It is held by some that the chief difference between a business and a profession is that the primal motive of the one is to take something away from society while the motive force of the other is to add something to that society. If this be so, it scarcely needs a mature mind to understand that social trends, as between business and profession, must at times collide and jostle one another threatening the outcome of, what is after all, a common cause.

Shut in, as the busy practitioner frequently is, by the multifarity of his own pressing professional activities, he often does not see what is going on beyond the narrow confines of his own horizon; he feels the pressure but he fails to sight the activating agency, over the way, at work.

In his busy caring for the physical body at hand he is prone to lose sight of the social body just yonder. He does not always realize that what the social body is doing beyond may be the very thing that is making the physical body, he is dealing with, so difficult a matter to serve justly and well.

If the physician has failed to secure that certain home for his soul that Emerson points to and Osler found to fulfillment, he is failing just now even more certainly to keep his earthly home in order and intact by his failure to read with discretion the passing history of the present moment as it is being recorded. It is quite as necessary for the medical man to know the social body as it is for him to know the physical body if he would keep his place in the former and do his full duty by the latter. It is quite as necessary for the good doctor not only to know diseases, but to know men. He must study not merely their physical processes, but the motives that guide them and the problems that beset them. These things he must know if he would see clearly and as a whole the civilization men have made, and of which he himself is.

At present the physician shows signs of not realizing at all what the leaders of our present social order have in store for him. It seems to be escaping him entirely that the social body in its industrial dress is discovering in him a very useful and profitable tool which is highly desirable from a financial point of view to have

incorporated with its own erstwhile activities. That he forfeits his own individuality and communal influence built up through the ages and through no self-seeking motives, is to the corporate interests of small concern.

The physician above all others, if he is to follow the high ideals of his professional past and meet the high ideals of his professional future, should know with great accuracy, just what the social body outside his small professional sphere is doing, if he hopes to protect his personal as well as his professional being. And he may not expect to accomplish this without an intelligent selection of his reading. His sources of information need to be sound and authentic.

The truth is, be it said to our professional chagrin, that all too often the medical man, for want of a little system, allows his life to become so involved in a round of unimportant activities that he has no leisure in which to acquire a broader wisdom and perspective. He ceases to be a citizen of the world.

Rumors float about that all doctors will be absorbed in a vast scheme of State medicine. They will be hired and fired like any other government employees. On the first of the month they will receive their pay envelopes like the rest.

Where has the dignity of our profession fallen? We who were once leaders are now to be hirelings. Must we keep reminding ourselves and the public of what a free and independent medical profession has given to civilization? That through the struggles and selfsacrifices of its individual members the sudden and most dreaded scourges of mankind have been wiped out or held in check? That whole countries have been made habitable places? That commerce can function only when supervised by its sanitary ruling? That cities can exist only by its protection of their water and milk supplies and its direction of public health? That warfare can only be waged by the assurance of its participation—or shall we say by its consent? Here, indeed, is a power and influence, as well as a value, that industrial or political leadership would like well enough to call its own. The tragedy is that others see what we do not.

It is time that the medical profession made a careful individual study of just what the social body outside its gates is aspiring to.

There have been two great profit-gathering periods in the history of civilization—that of ancient Rome, when the physicians were slaves, and recent America, where as yet their status has not been determined. The former, it is to be presumed, all cultured professional men are familiar with. The latter is now being vividly related in contemporary book form

and in the best of our magazines. If need be, the medical man should lay aside a portion of his other interests to acquaint himself with the rapidly moving and astonishing events of his own times and, on behalf of that welfare of which he alone is the capable custodian, stand ready to protect those traditions of large social value upon which he was nurtured.

It would be well for the medical men of this land and of this time to knit themselves together into a firm fabric that will withstand the certain subjugation of their individual members if they attempt to remain ununited. There are spiritual values as well as physical values woven into the cloth of which we are. Never, perhaps, was there more need than now to stand guardian over these sacred human assets menaced by a materialistic frenzy from without.

The physician is advantaged by a clearer appreciation of the limited mental age of the average citizen and, with his own better knowledge and understanding, a heavier responsibility rests upon him in this relaxed period of playthings and light mindedness provided by the machine. Alcohol is not the only intoxicant capable of upsetting mental balance and defeating the temperate and surer cultural advancement of the race. In the days of Sulla and Caesar slavery provided the setting for the self-indulgent and superficial life that machinery provides for us in these days of Rockefeller and Ford.

This is but a period, a season, in the transit of time; and the chances that it will land us in the same dark debacle as our predecessors is becoming ascendingly more probable unless we put into operation more intelligence than they did.

Our first necessity is to acquaint ourselves with the situation, and do it with the same energy and dispatch usually devoted to any problem confronting the first law of nature; it is, indeed, a matter of self-preservation for affairs are not moving slowly albeit they may seem silent and safely distant.

The medical profession should prepare it-self to take part in the world's work fully recognizing its own important place, its own power and influence in the present scheme of civilization. It should stand solidly upon its own feet and carefully reserve for itself the dispensation of its own contributions to the present pattern of society. It should do this, need it be said, from no selfish motives but in order to stay the forces inimical to those higher human values that the profession of medicine has always championed. It should advance its cause primarily by investing its interests in health and secondarily in meeting the problems of disease. To these high ends the physi-

cian must become acutely alive to the dominating tendencies of his own times.

Let us keep our eyes on what is being told in any two or three of the leading magazines and also watch for the books that sincerely chronicle the passing show. Study a cross section of any typical community by reading "Middletown" by Robert and Helen Lynd, for example, and see how prosperity "sets" on the stomach of every day American life.

"Our Business Civilization," by James Truslow Adams, is another book of revelation—and, by the way, when you see Mr. Adams ame attached to any recent book or magazine article dealing with social problems pounce on it as you would upon a precious stone, for it will ornament your understanding. In the past eighteen months he has appeared several times in Harper's Magazine. Not one of those papers should be missed. In the same magazine have appeared papers during the last year by such men as Albert Jay Nock, Harold J. Laski, and Stuart Chase. Hunt those writers out and let them clarify your mind on this important matter.

Scribner's, The Forum, Harper's, The Bookman, Century, The Atlantic, The Survey Graphic, The New Republic, The Outlook and Independent—these are the sort of magazine that marry your mind to the realities of our present period.

These few suggestions make a sound beginning for any of our profession who have not as yet got up an interest in this new national game of who can get the most money. In this game it is not always easy to descry the players who, bent on a vast superfluity of wealth, neatly screen their unwholesome acquisitiveness behind the utterance of platitudes or a display of concern in man's welfare.

Fortunately for humanity there are other things beside material accumulation which in the long haul are infinitely more worth while to the interests of mankind and, fortunately again, the vast majority of the men of our profession realized this or they never would have chosen the career they did,

What other profession is there that has the far reaching power and influence for good or evil possessed by the medical profession? We dip into every crevice of society and we reach to its every peak. Let us take a page from Osler's book and try, as he did, to fulfill our obligation of allegiance to the noblest calling of all. Let us stand together and above submission, and fight for the cause that leads man upward rather than, through our indifference, sink into a mere materialism with him. Let us lead, not follow, and to this end devote ourselves to such reading, as, rounding out our social sense and enlarging our vision to see life whole, fits us for the role of leadership.

# THE PSYCHO-ANALYSIS OF BORDER LINE CASES\*

By C. P. OBERNDORF, M.D., NEW YORK, N. Y.

AT the outset, it is best to define, so far as can be done, the terms percha and border line mental cases. The term psycho-analysis is legitimately used to denote three distinct concepts: (1) the school of psychology founded by Freud; (2) a method of psychological research; (3) a method of treatment of neurotic disorders. In this paper, we are concerned preponderatingly with the last application. However, in America especially, "psycho-analysis" is glibly used and vaguely applied to almost any form of psychotherapeusis, mind reading or palmistry.

"Border line mental case" is as indefinite as the indiscriminate use of the phrase psychoanalysis. In a general way in our estimation of human conduct, the average must serve as a norm-a shifting, varying, impermanent norm—and that norm shades off into the milder forms of neurotic conduct imperceptibly. Progressing a step beyond the realm of simple neuroses, between the severer neuroses and the milder psychoses, one also finds a merging of symptoms so that competent psychiatrists might differ in applying either the benign or malignant label to certain cases. The terms neuroses and psychoses, like the term insanity, are concepts which may be expanded or contracted within certain limitations. While a nomenclature is indispensable in order to convey very broadly the type of disorder under consideration, terminology in functional disorders admits a latitude which makes it possible for a goodly percentage of. cases to be pigeon-holed as either severe neuroses, mild schizophrenias or mild depressions.

The Kraepelinian descriptive nosology of psychotic manifestations represented a brilliant advance in psychiatric orientation at the time of its promulgation. It had barely become established in America about 1910, before the studies of the psycho-analytic school were well on the way to undermine its value. The work of Bleuler in Zurich, especially his theory of psychic ambivalency, directly instigated by the discoveries of Freud, the analysis of the association disorders of schizophrenia and his studies in autistic thinking, made, possible a psychological interpretation of the symptoms seen in schizophrenia. However, Bleuler clung to the concept of schizophrenia being the evidence of an organic disease of the brain. Notwithstanding this, in 1908, Karl Abraham,1 possibly the keenest clinician of the early group which joined Freud's standard and at the time under the direct influence of the

\*Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y., June 6, 1929.

\*Abraham, Karl: Klinische Beiträge zu Psycho-analyse, 1921—Internationale Psycho-analytic Verlag, Page 35.

Zurich clinic, stated that the "postulations of an abnormal psycho-sexual constitution in the sense of auto-erotism seem to me to explain a large part of the disease symptoms of dementia precox and make the recently elaborated toxin-hypothesis needless." Subsequently, in 1912, Abraham<sup>2</sup> analyzed a case of manic depressive insanity and called attention to the fact that the affect of depression is quite symptomatic of all forms of neuroses just as the affect of anxiety is present in most cases of depression. His formula of the psychic mechanism of depression is-I cannot love people, I must hate them. The second step in the process is a projection—namely people do not love me, they hate me because I am afflicted with certain congenital defects, therefore I am unhappy, depressed. at this time proposed the psycho-analysis of persons suffering from recurrent depressions in the interval between attacks as a prophylaxis against future recurrences. By this time, Freud himself had invaded the field of the psychoses with his ingenious psycho-analytic interpretation of the biography of a case of paranoia which he held to be due to the projection of an unconscious homosexual interest by the persecuted upon the persecutor. Shortly thereafter, he published his delicate differential study of "Mourning and Melancholia" which might, perhaps, he translated as grief and depression, in which he emphasized the ambivalent feelings of the depressed patient toward the lost love object.

The personality studies by Hoch and the formulation of psychological reaction types by Meyer in America, the latter's dynamic interpretation of mental disease, embody at a conscious level the dynamic principles of conflict between instinctual strivings and ego demands which Freud demonstrated to be the basis of so many neurotic disorders. Meyer still4 (1928) "prefers not to do very much more with the socalled unconscious but to work very much more with the facts as we find them." The valuable contributions which American psycho-analysts have made to the advancement of psychoanalytic knowledge are meager indeed and the few original ideas brought forth are not particularly well substantiated. However, very largely because psycho-analysis in America has been unswervingly sponsored by a group of well trained psychiatrists, the tendency to infuse psycho-analytic concepts into border line cases has been more general here than abroad.

<sup>&</sup>lt;sup>2</sup> Ibid.—Page 95. <sup>3</sup> Ibid.—Page 102. <sup>4</sup> Meyer, Adolf: American Journal of Psychiatry, Vol. VII— No. V—Page 940.

The position previously assumed in this paper indicates that there is no hard and fast line between neuroses and psychoses, that one finds schizophrenic reactions in compulsion neuroses, that compulsive activities complicate schizophrenias, that anxiety states quite constantly fuse with depressions, that conversion symptoms are found in depressions, in manic excitement as well as in hysterias, etc.

One may even carry this theme a bit further in questioning the desirability and validity Freud's own classification of neuroses into the psychoneuroses proper-namely, the conversion hysterias, compulsion neuroses and anxiety hysterias, on the one hand, and the actual neuroses-neurasthenias, hypochondrias and anxiety neuroses, on the other. Indeed pure cases of any of these types are so rare as to be negligiblefor neuroses as a rule are mixed. In private psychiatric practice, most of the semi-psychotic and psychotic functional pictures are so far removed from text book descriptions that the thought arises to what extent given functional diagnoses in closed institutions are forced and how much more difficult still it would be to force them into the established groupings were they studied more intensively.

Freuds has attempted to differentiate neurosis from psychosis on the basis of the reaction to reality. While the neurosis does not deny reality, it attempts to avoid some specific disagreeable phase of it and seeks to protect itself from contact with it. In contrast, the psychosis denies reality and seeks to replace it. Thus in the psychotic reaction some rejected portion of reality is reconstructed pathologically to meet the needs of the patient. Freud, however, recognizes that this differentiation is weakened in that in the neurosis there may be also attempts to substitute the undesired reality by a more acceptable fancied one. Let me quote briefly such a complex patho-

logical reaction:

The patient, at the time aged twenty-four, came for treatment following an attempt at suicide by drinking iodine which culminated an intense depression and almost continuous reflection over his intolerable personal situation day and night for a period of three months. He had suffered from a similar depression at the age of nineteen when he voluntarily discontinued his studies at one of the Catholic colleges where he was preparing for the priesthood and entered business. When the patient attempted suicide, he confessed to his brother that he had been driven to it by a conviction that he had been overwhelmed in his apparently hopeless struggle against sex. He had been raised in an extremely pious Catholic environment and it had been the fond hope of his parents that he would eventually be ordained. His psycho-sexual conflict began at the age of

\*Freud, S.: Zeitschrift für Psychoanalyse, Vol. X-No. 1-Pages 1-5, 1924.

The immediate cause for his despondency centered in a very unusual neurotic manifestation. He abandoned his studies for the priesthood after his first depression so as to be freed of the sexual restrictions inherent in that profession but upon attempting coitus some years later he found that he became afflicted with a sniffling of the nose whereupon his erection disappeared. As a matter of fact, the sniffling of the nose had constituted a tic like movement since the age of fifteen and if he had been committed to a state hospital it is quite possible that this tic in as much as it was associated with mental inaccessibility, would have been classified as a stereotypy or a grimace. Moreover, the patient's very bizarre, fantastic, interminable psycho-sexual religious phantasies, such as one finds coming to light only in very deteriorated dementia precox cases, would have easily justified a diagnosis of schizophrenia. He presented a disorder which in all probability at the hands of a non-analytically trained psychiatrist would have been diagnosed either a dementia precox or by some few, perhaps, in view of the ostensible recovery of the early depression. a depression of the manic depressive type. However, on the basis of his insight and contact with reality, the conversion symptom (nasal sniffling) was analyzed first. Later the phantasy formations and correlated depression were attacked and because of the handling of unconscious factors, a recovery has been effected.

It becomes almost automatic for the analytically trained physician to approach psychotic reactions as a whole in terms of evolution or regression of the individual's psychic structure in the face of intra-psychic situations-less cogently in response to environmental stress. For example, two months ago a woman, aged thirty-four, married. was referred for analysis because of fainting attacks occurring at rapidly increasing intervals. Her physician recognized them as hysterical and suspected their origin in a psychic conflict aggravated by a marital situation and correctly interpreted them as a flight from reality. He sent her to a hospital but two days elapsed before I saw her. At the first interview, for two solid hours long repressed psychic material gushed forth with a glow of hot lava. A full fledged manic attack, from which she has not yet recovered, ensued-but, with the surmounting of the repressing forces, the fainting attacks have

Likewise, the minutiæ of psychotic reactions supplement and elucidate the factors operative in the reaction as a whole in the appearance of individualistic symbols, substitutions, sublimations, projections, displacements and overcompensations—the significance of which is so often totally unconscious to the patient.

While often emphasizing the importance of psychogenic factors in the production of organic disease and psychoses, the psycho-analyst does

not ignore either biological causation or process in mental disease. Admittedly, psychoses are often set in motion by many types of pathological processes causing temporary or permanent damage to the brain-tumors, scleroses, endogenous or exogenous toxins, etc. But even in such cases the content of the process serves as a basis for intelligent insight into the structure of personality. For example, the content of hallucinatory experiences, whether induced by drugs such as ether or the elevated temperature or without demonstrable cause, probably represent some purpose satisfying to the psychic economy of the individual." That the visual hallucinations produced by alcohol in men (snakes, elephants with huge trunks, mice, etc.-phallic symbols) are often identical in alcoholic patients is not to be construed as evidence that alcohol produces a specific type of hallucination but that in the minds of many males addicted to alcohol the same fullness of repressed homosexual fixation exists. Several competent observers have assured me that no similar hallucinations are customary in female alcoholics. So too, no matter what the instigating process of the pathological mental state may be in psychotic states, analysis may show that the delusion of persecution is closely connected with a primal thwarted love attachment to the persecutor, that alcoholism is not explicable upon hereditary, environmental or educational grounds alone but represents a flight from and indulgence in certain libidinous cravings, that in melancholia the self reproaches are due to an ambivalence in regard to the lost love object and that the reproach is directed not against self but against an image of the love object incorporated in the ego, that in manic phases in his garrulousness and elation the patient rises above his inhibitions and rides care free upon the top of the world as he did before society imposed its irksome restrictions upon his conduct.

The criteria for the advisability of making an analytic approach with some hope of therapeutic success in psychotic disorders are three-foldnamely, the degree and stability of the transference, the depth, persistence and clarity of insight. and the degree to which the patient in his mental disorder denies reality. The term transference, usually corrupted to indicate any form of rapport between patient and physician, is used here in its strict psycho-analytic sense, i.e., the unconscious displacement of an affect, either positive or negative, from a person who at one time played an important affective role in the patient's life, upon the analyst in the course of the patient's contact with him. While it would seem extremely difficult to utilize negative transference to a therapeutic end in the case of a pschotic patient it is conceivable that an inconstant negative transference might, with sufficient patience and insight on the part of the psychiatrist, be employed as an entering wedge for contact in a case of mild schizophrenia. In this latter class of patients who remain so persistently at or have regressed to an auto-erotic level, a dependency transference in which the physician plays the role of the nursing mother can often be immediately established.

So too, a certain degree of insight is probably never entirely absent in either schizophrenias or manic depressives, although varyingly reliable at different phases of these disorders. Withdrawal from reality is rarely complete, notwithstanding the apparent isolation of the schizophrenic who sits rigidly, drooling, in a chair but who may astonish one by spontaneously making some very pertinent comment about the examining physician or his environment. Obviously, in determining the advisability of therapeutic approach, the proportionate retention of these three qualities-transference, insight and denial of reality—must be ascertained and the physician might hazard the undertaking of the analytic treatment of a case in which one of the factors, such as transference, was extremely propitious whereas the other two were meager at the outset.

On the basis of these criteria obviously the incipient case of schizophrenia and mild, undifferentiated depression are the psychotic disorders most amenable to readjustment through the psycho-analytic approach. In such situations the orthodox method of psycho-analysis must be altered very widely, particularly in the matter of expression of greater sympathy, advice and encouragement of the patient on the part of the analyst, and greater caution in intimating the underlying unconscious causes for the pathological symptoms. Perhaps even a conscious effort on the part of the analyst to encourage the identification of the patient with himself is permissible. Often a lack of understanding and an environmental situation in the home make it desirable and even imperative that these patients be removed. Here, I would make a plea that the State establish a home or house for such mild psychotics to forestall their entrance to a closed institution. Such patients when their mental conditions permitted could pursue their occupations and be treated in a State sustained clinic located apart from such a home just as the wealthier individuals are allowed to reside in the community to their great advantage, I think, and obtain treatment at the hands of private practitioners.

In the analysis of most psycho-analysts, an unconscious ambivalence to the subject they so zealously advocate and pursue is almost invariably demonstrable. The same is probably true of psychiatrists in general who occasionally have been heard to utter remarks of disparagement, deprecation and disgust in regard to their patients. If we can free ourselves from such unconscious hostility, following the Freudian for-

<sup>\*</sup>Oberndorf, C. P.: A Case of Hallucinosis Induced by Repression. Jour. of Abnormal Psychology, February, 1912.

mula we may run less danger of falling into a state of depressing self reproach and its concomitant mental retardation and psychic paralysis in connection with functional disorders. In similar vein, I would close with one of Freud's pithy, epigrammatic remarks voicing a guiding principle particularly well suited for psychiatric attitude if we are to progress in the understanding of our mystifying specialty, namely, "if we cannot see clearly, let us at least see what is unclear clearly"

## TRACHEOBRONCHIAL ADENITIS\*

# By CHARLES P. EMERSON, M.D., INDIANAPOLIS, INDIANA

AMONG the shadows on chest films few have attracted more attention than those in the hila of the lungs, sometimes so conspicuous, so frequently present in apparently well persons, and, except in children, usually so little related to the active processes present in the case.

Along the lower trachea, at the bifurcation of the primary bronchi, and along the larger bronchi are groups of lymph-nodes which may play a large part in the pathology of chronic pulmonary conditions. These nodes may be divided into three groups; the tracheal nodes, seven to ten in number, located along both sides of the lower trachea; the bronchial nodes, larger than the above, and from ten to twelve in number, at the angle of the primary bronchi; and the pulmonary nodes, smaller but more numerous, imbedded along the bronchi in the hila of the lungs. These lymph-nodes receive afferent vessels from the lower trachera, the lungs and their bronchi, while their efferent vessels run upwards toward the neck.

Only two or three years ago the roentgenologists, with much improved technic (Granger's method) in visualizing the conditions of the nasal sinuscs, demonstrated their ability to diagnose the presence of an unsuspected nasal sinusitis from the appearance of these hilum shadows alone. Also, it is since that time they have emphasized more than ever the importance of infections of the posterior sinuses, that is, of the posterior ethmoidal and sphenoidal sinuses. These sinuses have often been disregarded since their ostia can seldom be seen on direct inspecton of the nose and they cannot be transilluminated. It would be foolish to pronounce these more important than the anterior sinuses, nevertheless, because of their size and position, they must be quite important in the pathology of general infection. They deserve especially mention also because they may harbor serious infection when the nose on direct inspection and on transillumination may appear quite normal.

The lymph flow from the nasal sinuses would seem to be by way of the deep superior, inferior cervical, and retropharyngeal lymph channels directly into the thoracic duct at the root of the neck. Whether or not they can drain directly to

\*Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y., June 4, 1929.

the tracheobronchial lymph-nodes is doubtful. Certainly under normal conditions the lymph flows from the head and that from the hila of the lungs would seem to converge towards the left sternoclavicular articulation. Clinically, however, one is tempted to assume that the infection from the sinuses reaches directly the tracheobronchial nodes. More likely, however, these nodes are infected by repeated descending infections of the mucous membrane from the upper respiratory passages to the trachea and bronchi, the so-called recurring colds, "slight flus," and "grippes," which these patients have; or, receive their infection directly from the bronchial mucosa which had been infected by way of the pulmonary circulation. Nevertheless, under pathological conditions the lymph flow does establish unusual routes, and a direct flow from the head to the hila is by no means an impossibility.

Since the great influenza epidemic sinusitis has demanded much more attention than ever before. Indeed, influenza has been well named "epidemic sinusitis" because of the almost constant early localization of this infection in these cavities, and because of its almost constant sequela, chronic This latter is not, however, of the sinusitis. purulent type, but the sinus mucosa undergoes a slow hyperplasia which produces a thick mucosa. perhaps more injurious than a sinus empyema, since freely flowing pus is, after all, an irrigating fluid which starts in the tissue spaces themselves and washes out the products of infection, which no local therapeutic irrigation could possibly do. We have always felt that the partiality of the Middle Ages for "laudable pus" does not now receive nearly the respect it deserves, for in those centuries preceding aseptic and antiseptic surgery a free flow of pus must certainly have washed out from the wound many germs, including Bacillus tetani, which later would kill the patient.

Tracheobronchial adenitis is often referred to as "mediastinitis," an unfortunate term since indefinite and also untrue, for many of these nodes are imbedded in the lung tissue of the hila. It is these nodes which are the starting point of many of the cases of so-called central pneumonia, or bronchopneumonia, so common during and after the influenza epidemic. These were the cases with uncertain physical signs—now a hint of pneumonia on one side, tomorrow on the other, later

on both, some days on neither, which worry the physician so much, who feels confident from general symptoms that the condition must be a pncumonia and yet is unable clearly to demonstrate it. These pneumonias, however, are really a form of pneumonitis or interstitial pneumonia. The term pneumonia should be reserved for primary infections of the alveolar epithelium such as are caused by Diplococcus pneumonii. Such a pneumonia is a true surface disease since the exudate is entirely on the surface of the body; that is, is within the air cells of the alveoli whose epithelium is a surface membrane. In the hilum pneumonia we are describing there is, in addition to consolidation in the air cells, an inflammation which involves also the interlobular tissues. Hence it is that resolution is quite slow. presence of these infected nodes in direct proximity to the wall of the trachea or primary bronchi produces an inflammation which extends directly through to their mucosa, and explain the paroxysms of hard dry cough, often worse at night, often suggesting the paroxysms of whooping cough, and often so violent that the patient fears that his lung may be ruptured. The character of this cough suggests a foreign body within the bronchi which if it were present would produce a somewhat similar lesion of the nucosa. These coughs are usually dry, and yet may raise a little mucus, but this alone gives little relief. Such a cough may persist for months. It is more than possible that many cases of chronic bronchitis owe their origin and continued existence to these infected lymph-nodes. This would seem particularly true of those cases of bronchitis which depend so immediately upon changes of weather, a point which suggests the sinuses as the starting point of the infection. These patients claim to have "flu" or "grippe" each winter. They say that they "catch cold easily," which means that they have the same cold all the time, but one which easily becomes acute.

These tracheobronchial lymph-nodes, although not now tuberculous, have earlier undergone calcification and form some of the so-called lung stones, which set free by secondary infection, ulcerate into the neighboring bronchus. At such a time the patient who previously has enjoyed good health suddenly develops a particularly aggravting, dry cough, with afternoon fever. He loses weight and strength, and in a few days suddenly coughs up some pus, following which he feels at once better. If the calcification is soft the incident is soon forgotten, although some patients do notice that some of the sputum is gritty; but if hard, the patient, following often a sudden hemorrhage, suddenly suffers a bronchial colic of excruciating pain, and expectorates one or several calcified masses.

These infected tracheobronchial lymph-nodes may explain also many, and possibly most, of

the pulmonary hilum abscesses, which are more common, perhaps, than we have assumed. In these cases the patient, following an uncertain fever of one or more weeks duration, suddenly expectorates a cupful of pus. After several such evacuations these abscesses may completely heal.

The infection which spreads from these nodes to the hilum and along the bronchi easily explains, together with the resulting recurring chronic bronchitis, some cases of bronchiectasis.

In diagnosis the history of frequent attacks of "influenza" or "grippe," attacks of severe dry, coughing, and the development of chronic bronchitis, frequent hilum pneumonia, bronchiectasis and hilum abscess suggest tracheobronchial aden-Their shadows on the x-ray plate are often itis. very suggestive of the condition, but we may overlook them unless good lateral plates are made, since in the anteroposterior plates the shadows of the spine, aorta, and nodes are superimposed. Since the shadows of chronically infected and calcified nodes are permanent, and therefore when present cannot be interpreted as necessarily the sources of the then present infection, there is need of careful study of the sinuses and careful consideration of the clinical features of the case before assuming their importance at any particular time. A marked D'Espine test is suggestive. of our cases our associate, Dr. J. F. Barnhill, the otolaryngologist, was able through the bronchoscope to see the inflamed spot on the mucosa of a primary bronchus, and by local treatment to hasten the evacuation of the lung stone.

In the treatment of tracheobronchial adenitis we have used moderate x-ray therapy with great success. One should first assure himself that the sinuses are at least quiescent. Cod liver oil, syrup of the iodide of iron, tonic treatment of all kinds, full diet, and especially a change of climate all have their value in these cases.

Of course the infected sinuses will demand adequate and persistent attention. their surgical care we can say little, except that the opening of the nasal passages by submucous resection of the septum or of a turbinate usually is sufficient. After this is done the care of the sinuses themselves is well handled by drops, the patient lying across a bed, his head hanging over the edge and bent back to over a right angle. First, one instills into each nostril three drops of 1% ephedrine solution followed by eight drops of 1 to 8000 mercurophen or of 10% argyrol solution (the ephedrine and mercurophen solution should be made up with physiological salt solution, not distilled water, since the effect of the latter may be painful). (Our colleague Dr. Ernest deWolfe Wales has taught this treatment.) Many cases fail because the neck is not bent back quite far enough, and the drops, instead of reaching the superior meatus, flow along the middle meatus to the posterior nares.

Annual meeting June 2-4, 1930, Hotel Seneca, Rochester, N. Y.

# DAYLIGHT SAVING TIME AT THE ANNUAL MEETING

The City of Rochester has gone on daylight saving time within the last fortnight. All the meetings of the Medical Society of the State of New York will therefore be held according to the daylight saving schedule. This means that the times of assembly will be one hour sooner than those announced in the programs

sent to the members. The principal inconvenience will be to those who are arranging their railroad schedule so as to arrive at a definite hour. But whatever the technical hours may be, a pleasant and profitable time is assured to everybody who attends the annual meeting on June 2-4, 1930.

# UNITY OF MEDICAL EDUCATION

Medical education is a never-ending process, beginning with the premedical college courses in sciences and mathematics, and continuing as long as the physician remains in active practice. Yet every practising physician is likely to think of his medical career as constituted of three stages:

- 1. The medical school.
- 2. The interneship.
- 3. The rest of his medical life.

There is a tendency for doctors to separate these stages in fact as well as in thought. The medical school quickly becomes a sublimated memory of strange names and of mysterious processes only dimly understood and of little practical application in the practice of medicine. The interneship is recalled as a nightmare of laboratory reactions and ponderous tomes of dry records and statistics. When the fledgling doctor tries his wings alone and finds that he can soar unhindered and unnoticed, he is likely to leave the training nest behind him and fly away on his own career of medical independence. The interneship and the medical school are too often but far off memories to the practising physician; and yet the doctor who is respected by his fellows never ceases to study. His hospital takes the place of his medical school, and his medical society becomes his fraternity and club where he finds pleasure, information, and inspiration.

The leaders in medicine today are the modern products of the spirit of the medical school incarnated in medical practitioners; and the great mass of physicians are now eager to sit at the feet of their teachers in graduate courses which bridge the gulf formerly existing between the medical school and the medical society.

The methods of the medical school are needed in graduate education; and on the other

hand students in the medical schools need to catch a vision of the clinical experience to which later they will be introduced. The Yale Medical School recognizes this need by providing simple clinical demonstrations at the beginning of the course so that first-year men will see the application of anatomy, physiology and chemistry to the actual practice of medicine. Some medical schools give their course in physical diagnosis to second-year men who thereby approach the clinical teaching of the third year with the basic knowledge which enables them to profit at once by what they see and hear in the sick room.

Reversing the process, those giving moderr graduate courses find it necessary to teach the principles of the elementary sciences which apply to the condition under discussion. The fourth year medical students and the internes can often profit by a graduate course to a greater extent than the practitioner who has forgotten his elementary science. One characteristic of the modern doctor is that he carries the spirit of the medical school into his practice of medicine.

The Medical Society of the State of New York as well as the societies of most other states are making graduate education one of their major activities. In them the physicians are all students again, living over their experiences of the medical school

riences of the medical school.

It is an excellent omen that many of the graduate courses are sponsored by the medical schools whose professors profit by first-hand contact with their sophisticated students. Moreover, the practitioner student becomes meek and receptive as he sees the practical results which research men have accomplished in the cloistered school. It is a good sign of the times that medical societies and medical schools are merging into a unified system of medical education.

## HOSPITAL CENTERS

The practice of medicine consists in giving medical service to the people. Physicians have standard ways of giving that service. The great majority of doctors give their services as individual physicians to individual patients; and the system works with efficiency when it is handled intelligently.

Neither the law nor medical custom requires the doctor to give the highest type of scientific medical service to his patients. The doctor is expected to give service along the broad lines of diagnosis and treatment which are available in his locality. Many diagnostic measures are not available outside of urban centers of population. The ordinary practitioner is not expected, for example, to own an x-ray machine or an apparatus for making chemical blood analyses. Neither is he expected to have the diagnostic ability to judge rare diseases such as tularemia. He seeks the help of a specialist for the more uncommon conditions; but the eye specialist is not expected to be an expert on fractures, nor the neurologist to make blood sugar determinations. A physician who con-

EDITORIAL 655

scientiously wishes to make the more uncommon diagnostic tests must seek the services of not one specialist, but several.

The question further arises—how much should a general practitioner be expected to know. Experience has shown a practical answer in most cases. Dr. Billings says that a general practitioner should be expected to make a correct diagnosis and give the proper treatment in ninety-five per cent of his patients. It is the remaining five per cent that puzzles him and leads to misunderstandings and dissatisfactions.

Doctors throughout the land are solving the problem of diagnosing and treating problem cases by means of hospital centers. Every general hospital has the possibility of being such a center through its laboratories and the cooperation of members of its staff who prepare themselves by intensive study along certain lines. There are enough general practitioners available on every hospital staff to give proper

medical service in the great majority of problem cases. A few obscure cases will require still more special knowledge which will be supplied by a consulting staff. There is no difficulty in securing a list of skilled consultants who will be available for the few difficult cases which the staff cannot handle.

Every section of New York State is so well supplied with hospitals that skilled attention is available to every person. The new welfare law of the State requires the welfare officers to offer medical service to every citizen who is unable to pay for the service. The law is new and has not been thoroughly tried; but it at least removes the excuse of poverty from both the doctor and the patient.

The patient who needs medical service can find it in the hospitals of New York State provided the proper means are adopted for securing it. Both doctors and the people need to study the law and follow the procedures which it prescribes.

#### LOOKING BACKWARD

### This Journal Twenty-Five Years Ago

Interest in Civic Medicine: Mr. Edward Bok, editor of the Ladies' Home Journal, addressed a letter to the medical profession, which is printed in this JOURNAL of June, 1905, and in which he scolds the physicians for not cooperating with him in his efforts to control patent medicine advertising, Mr. Bok said:

"During the past winter there were introduced into the Legislatures of not less than fourteen States bills which had for their object the regulation of the sales of injurious patent medicines, or the compulsory printing of the ingredients of those medicines on the label of each bottle, under penalty of fine on conviction.

"Committee hearings were given on these bills in each State. The proprietors of some of the patent medicines were exceedingly active—and effectively so—in their opposition to these bills. Associations interested in the patent-medicine traffic worked with unceasing vigil to defeat the bills—which they succeeded in doing.

"Now, who appeared in favor of the bills at these hearings? Generally, members of the

Woman's Christian Temperance Union, whose zeal usually exceeded their discretion and judgment—well-intentioned, but ineffective. In one or two cases representatives of some liquor dealers' association appeared in behalf of the bills. But not in a single instance, and I speak by authority of personal representation at each of these hearings, did there appear a single physician or the representative of a single State, county or city medical association. There was not the slightest active interest taken by physicians in these hearings, and yet scores of physicians wrote me irate letters after the bills were defeated, deploring the corruption (?) of the Legislatures in their States!

"The Ladics' Home Journal entered on its editorial treatment of the patent-medicine curse from principle and from no other motive. Its only interest is the interest of the great public at large, not the commendation either of it or its editor. Both have received that at the hands of the medical profession. It now asks that the hands of the profession works, not words."

# 2

# MEDICAL PROGRESS

The Relation of Diet to Health and Disease. -Edward Mellanby submits evidence showing that diet, in addition to supplying material for growth, maintenance of the body, and energy for the performance of work, also contains two groups of substances—one which tends to produce pathological changes and ill health, and the other which helps to protect against toxic factors and other disease-producing agents, such as microorganisms. It has been shown that well calcified teeth can be produced by the ingestion of sufficient vitamin D, and that such teeth are less susceptible to caries than badly calcified teeth. Cereals seriously interfere with the deposition of calcium salts in bones and teeth. Oatmeal is the worst of all the cereals examined, and white flour interferes least with the calcifying process. studying the action of cereals on the formation of bone, it was found that some of the dogs developed severe incoordination of movement. and that examination of the nervous system of these animals showed scattered degeneration of the cord. This change was found especially in animals whose diet included the germ or embryo of grains, and was found only in animals receiving a diet deficient in fatsoluble vitamins. Mellanby has introduced the term "toxamin" to describe this substance found in grains which has a harmful effect and can be antagonized by specific vitamins. It seems possible that ergotism of the nervous system can be prevented in human beings by the inclusion in the diet of sufficient sources of vitamin A. The three other conditions best recognized in which subacute degeneration of the cord arises are lathyrism, pellagra, and pernicious anemia, and the question may be raised whether the degeneration in the cord may not be associated with a toxamin. In lathyrism the substance may be a toxin in lathyrus peas; in pellagra possibly it is a substance in maize. The cord degeneration found in pernicious anemia and the changes produced in dogs by cereals, in the absence of vitamin A, suggests a similarity in etiology. Furthermore pernicious anemia is brought under control by liver and water-soluble extracts of liver. The nerve degeneration of ergotism and that produced by the wheat embryo can be prevented or, if developed, the condition can be improved by the fat-soluble portion of liver. It is suggested that possibly the blood changes and cord degeneration in pernicious anemia are due to failure on the part of the liver, caused by a deficiency of a specific fat-soluble sub-stance, vitamin A. Observations made in a

series of cases of septicemia supply convincing evidence that vitamin A is an effective factor in preventing bacterial invasion and in overcoming septicemia.—British Medical Journal, April 12, 1930, i, 3614.

Relationship Between Endocrines, Infection, and Wound Healing.—H. J. Lauber believes that there should be a definite relationship between readiness for infection and the endocrine balance and that this might also be evident in wound healing. We know that in underfunction of the pancreas there is a marked predisposition to furunculosis due to the staphylococcus or streptococcus and that insulin will correct this tendency by increasing resistance. In seeking for analogous relationships in other incretory conditions he mentions that before menstruation some women have a subfebrile temperature, which may be due, he thinks, to a mild infection in the respiratory tract. He has seen cases in which the temperature was febrile and the infection beyond doubt, and even in these patients ovarian extract appeared to exert a specific action, when given as a prophylactic. In other words it is a good rule if the case is suspicious to give the extract two weeks before the menses for in so doing we apparently prevent the development of these mild or more severe infections. Some of these women who have been unable to work during the menstrual period have been restored to full activity in this manner. In regard to the thyroid he cites a case in a woman of notably hypothyroid constitution who sustained a wound on the back of the hand. It had been properly dressed and should have healed by primary union but suppurated with the development of lymphangitis and a temperature of 104° F. Healing even by second intention was frustrated, but six weeks later when the author saw the patient he placed her on thyroxin tablets and the wound healed in 12 days. author has no knowledge of any such association between infection and the other incretory glands. In a patient with unsatisfactory wound healing but without any evidence of incretory deficiency he tested a polyvalent treatment. The patient was a woman of 23, fat, who in theory might have had a defective formation of thyroid and ovarian hormone and who improved well on the two extracts. Analogous cases are also quoted.—Münchener medizinische Wochenschrift, March 14, 1930.

Noma of the Cheek.—Dr. J. Friedmann, in reporting a fatal cause of this affection, states

his belief that it is far less common than many years ago. Thus in one clinic in St. Petersburg (now Leningrad) 47 cases were recorded between 1870 and 1887. Today, although one may go back for a generation or more, only scattered cases are found recorded in the proper clinics, while the autopsy material is equally rare. At the otolaryngological clinic at Basle, the author found mention of but one case in the past 32 years, the one reported here, which occurred in 1926. The age was 17 months, the case far advanced when first seen, and there was great destruction of tissue before the fatal ending. No pathogenic organism or other causal agency could be located and treatment was of no avail. The theory that noma is due to trophic influence and is akin to decubitus gangrene, lead the author to study the trigeminus nerve which did indeed seem to be inflamed although perhaps secondarily. The theory of localized thrombophlebitis was also considered. Although some of the more recent cases seem to pursue a mild course and although not a few cases, mild and severe, seem to yield to treatment of one or another kind, noma still figures as a deadly disease because of the liability to such complications as aspiration pneumonia, toxic heart failure, and severe gastroenteric involvement, from swallowing the putrid secretions. places the mortality at from 70 to 80 per cent, which may be a slight improvement over the The amount of local damage which can be set up is in contrast to the constitutional symptoms of some of the patients. Thus gangrene has involved the ear of the affected side and even the brain may be exposed. In one recorded case in an adult the disease lasted for 8 months. Cures have been obtained by resection, electrocoagulation, curettage, salvarsan, and chemical caustics but also from mild applications and even spontaneous recovery is not unknown. The rapid development of facial surgery should favor cosmetic results .- Schweizerische medizinische Wochenschrift, March 22, 1930.

Treatment of Vincent's Angina.—George O. Cummings, on the basis of an experience with some 150 cases of Vincent's angina suggests the following outline of treatment: During the stage of invasion, if there are constitutional symptoms, the patient should be kept in bed and treated with laxatives, antiseptics, and a bland diet. Either hot or cold packs may be used on painful swollen glands. Although mouth washes are of little avail, they afford comfort for the time being, and it is well to prescribe them. They should contain some astringent, such as potassium chlorate, tincture of myrrh, or glycerite of tannic acid, for the purpose of diminishing salivation. Topical appropose of diminishing salivation.

plications are of value in only the milder ca as they do not get into the gingival st about the teeth. This should be flushed with a syringe having a blunt-pointed ne set at an angle with the long axis of syringe. As the needle follows around gingival sulcus, pressure is slowly application the plunger of the syringe, so that not onl necrotic débris washed out but mild antiser are applied to the diseased area. For this pose a 1:500 solution of metaphen or hexy sorcinol solution S. T. 37 is efficient. treatment should be carried out daily or ev other day, until the condition quiets do The patient should use sodium perborate home. This should be applied with the fir or a soft toothbrush, and should be used a dentifrice for some time after the symptom of angina have disappeared. In subacute chronic cases to avoid reinfection the pat should have three toothbrushes, which i be used in rotation, one soaking in a solu of chlorazene, or other mild antiseptic. drying, and one in use. When the disc affects the tonsils, the ulcerated area sho be wiped free of necrotic tissue and some a septic applied. The author has found chro acid more effective than any other drug, thou mercurochrome, metaphen, or hexylresore may be used. He does not feel that a pati having early symptoms and signs of Vince angina should be treated with salvarsan travenously until the simpler local treatme have been tried. In severe cases in which Ic treatment and salvarsan have failed, intrav ous injections of 5 c. c. of 1 per cent solut of antimony and potassium tartrate may tried .- New England Journal of Medicine, A 17, 1930, ccii, 16.

Nature of Kuemmel's Disease.-R. Leri states that some surgeons even deny the istence of this malady. Kuemmel who f isolated it in 1891 does not seem to be a to explain its nature and merely suggest trophic origin. The present author belie that it may be explained through what already know of ankylosing spondylosis. sums up the entire problem under four her Is there always a history of an old fractu The röntgen plates daily show us that fr ture of the spine may exist without caus symptoms at the time and we know also t a slight trauma may produce the most serie consequences. For some years after Kuemi isolated the condition we had no radiograp and he naturally did not associate the conditi with past fracture. Second, why should t disease be painful? The answer to this que is purely speculative and only hypotheses m be offered. Leriche considers several of the but seems unable to reach any definite co clusion. Third, can one prevent the appearance of this affection? The author speaks of the advantages, after any sort of injury to the spine, of immobilization of the latter and discusses routine surgical intervention to secure ankylosis, but thinks the risk too great. He has operated five times in all, in cases where the special indication was present, in other words in selected cases and his results in four have been excellent, the fifth case being too recent to include with the others. after Kuemmel's disease has developed, what is the best treatment? The answer is simple and direct—he would perform the bone grafting operation. The implanted bone graft should be both long and rigid. Rarefaction of bone is not a contraindication, for there is a good prospect of recalcification. no guarantee that the disease will always respond to the treatment. Immobilization and recalcification are not enough, for there is a tendency to hyperemia which must be checked. The author discusses the addition of sympathectomy to the other resources. Although he makes use of Albee's operation he makes no mention of his name.-Lyon Chirurgical, January-February, 1930.

Damage Caused to the Eye by Strong Light. -George H. Mathewson has had the opportunity to see a number of cases in which the eye has been damaged by strong light and has been impressed by the similarity of the ocular lesions produced by the different agents-sunlight, light reflected from snow, electric light flash, charcoal flash (the light produced when charcoal and gases in a retort take fire). The structures affected were the skin of the eyelids, the conjunctiva, the cornea, and the retina, but in no instance were all these parts affected in the same individual. In snow blindness there was superficial burning of the skin of the lids and face and the conjunctiva, with shallow nicers of the cornea. The electric light burns in some cases showed conjunctivitis, with slight burn of the cornea, while in others there were superficial ulcers, like those seen in sun blind-The symptoms in both of the above conditions, as well as in the charcoal flash burn, were chiefly photophobia and intense pain. In all these burns the use of simple vaseline in the eyes and protection from light relieved the pain, and recovery was prompt and perfect. Looking at the sun in eclipse produced lesions on the retina, seemingly a burn of the macula. Subjectively the only symptom was diminution of central vision, which varied from transient hazing to prolonged and permanent damage. There were dots of pigment and small white

of atrophy scattered about the macular and in one case permanent loss of , '-ion. A similar lesion was produced

in a case of acetylene gas burn.—Canadian Medical Association Journal, April, 1930, xxii, 4.

Treatment of Obliteration of the Central Artery of the Retina .- J. Rosnoblet distinguishes between the complete and incomplete forms. The former was ascribed originally to embolism, but in reality is due to several causes, as thrombosis, obliterative endarteritis, and persistent spasm. In the incomplete form the cause is angiospastic. In the embolic form there is sudden and total monocular blindness. If the causal agency is angiospasm the perception of light is conserved as is also the photomotor reflex. The author has had six personal cases and has studied the material of colleagues. In all the cause was angiospasm and the obstruction incomplete, the complete type being of excessive rarity. therapeutic angle the author divides his material into acute and incomplete. In the former something must be done quickly and the author recommends inhalations of nitrite of amyl and retrobulbar injections of atropine. Other measures which have given good results comprise massage of the bulb, division of the external rectus, and iridectomy. As glaucoma may be a sequela one may also make some use of miotics. However the author admits that this condition is but little amenable to treatment and that success is the exception. In the incomplete type the same remedies are directed against the angiospasm—amyl nitrite, atropine, and the recently introduced acetylcholin. There may be a causal indication in the form of hypertension due to nephritis, of syphilis, etc. A case is related of acute total loss of sight in a woman of 53 of 10 days duration. Examination of the fundus showed total obliteration of the central artery, evidently due to obliterative endarteritis (pseudoembolic The other eye had long been blind type). from optic atrophy. The author instilled dionine, and ordered nitrite of amyl inhalations. No time was lost on a Wassermann which later was found positive, but intravenous injections of cyanate of mercury were at once begun, and the patient entirely recovered the sight of the affected eye.-Le Journal de Médecine de Lyon, March 20, 1930.

The Serum Treatment of Pneumonia.—Professor Morawitz of Leipzig treated over 100 cases during the winter of 1928-29 representing both ordinary pneumococcus and grippe pneumonia. In the latter both polyvalent pneumococcus and grippe sera were used. The intramuscular route was always chosen and naturally the cases were selected, being taken early in the disease. There was no control to show superiority but the author had the impression that he saved life in some of the severe cases.

No attempt was made to type the pneumococcus patients according to the pathogen concerned. Statistics are not given. Professor Volhard treated 41 cases during 1929, typing them all and giving the indicated specific serum in each case. About half required a polyvalent serum. Tests for anaphylaxis were always made first and both intravenous and intramuscular routes were used. The doses were large. The author was unable to convince himself of any specific action and in no case was the pulse improved. There was evidently the usual mortality although the author gives no statistics. More recently he has used an American serum which seems to promise specific effects. But the author will probably depend chiefly on quinine and urethan as heretofore. Professor F. Meyer of Berlin has used serum since 1916 but in connection with some of the quinine derivatives and is satisfied that this combination is the best treatment we have. He gives no figures. In addition Dr. A. Sonnenfeld of Berlin contributes a special paper on the subject. The interest in the serum treatment in America and the favorable results obtained have served to bring the subject especially before the German clinicians, but the author, like many others, seems disappointed with results obtained in his cases.-Deutsche medizinische Wochenschrift, April 4, 1930.

The Inhalation of Pure Oxygen in the Treatment of Disease.-Though considerable research has been done on therapy with 40 to 60 per cent, oxygen, the value of inhaling pure oxygen for long periods has not heretofore been investigated. John H. Evans has studied the effects of the inhalation of 100 per cent oxygen, using a face mask or a nasal inhaler. In a series of 143 cases of pneumonia treated by this method in all of which the prospects of recovery were very doubtful or nil, the death rate was 482 per cent. In 24 cases oxygen therapy was begun on the first day; among this group there were 23 recoveries and one death. The gratifying result shown in these cases deserves consideration, especially in view of the fact that the patients were nearly all seriously ill. The old custom has been to administer oxygen in low concentrations late in the disease, whereas the converse should be the case, namely, to administer oxygen in high concentrations early in the disease, as this helps to support the heart and permits a reduction in the dosage of the usual supportive medication. The intravenous administration of glucose in toxic cases has helped to save some of these patients. The plan consisted in the administration of pure oxygen continuously for the first twelve hours, whether or not cyanosis was present. If there was none, oxygen was given for from twenty to thirty

minutes each hour, if the patient was not asleep. When there was cyanosis the administration was continuous. The daily inhalation of pure oxygen has proved useful not only in anoxemia, but in a number of pathological conditions where there is no apparent lack of oxygen in the blood. It has proved beneficial in cases of cardiac decompensation, asthma, hay fever, influenza, extensive burns, pulmonary embolism, and hyperthyroidism. The administration of pure oxygen in order to be successful should be in charge of one familiar with the physiology and pathology of respiration and accustomed to the administration of compressed gases. The anesthetist is already in possession of the main requirements for the application of oxygen therapy.-Canadian Medical Association Journal, April, 1930, xxii, 4.

Diagnosis of Beginning Sclerosis of the Kidnevs.-Professor Erwin Becher of the Volhard internist clinic, Frankfurt, attempts to answer this query in a new fashion. Volhard has shown that in this affection the clinical picture exhibits much variation. Death may occur from apoplexy, pneumonia, cardiac insufficiency, uremia, etc. On the other hand blood tests do not show clearly when sclerosis passes into renal inadequacy. They differ notably in contracting kidneys and in acute nephritis. In the latter, at least until anuria is threatened, the aromatic group-intestinal putrefactive products-escape normally from the blood into the urine. The coloring matter also passes. In contracting kidneys after insufficiency has developed there is a precocious increase in the urinary aromatics, the color of the urine is pale, and the density does not exceed 1010. In acute nephritis the blood urea is increased early while in contracting kidneys it remains normal for a considerable interval. Hence in the latter affection the ratio between the retained urea and the amount of aromatic substances in the blood should be followed up. The author makes an important distinction between benign and malignant sclerosis, the former having a natural tendency to terminate in the latter. The transition between the two is indicated when there is a gradual increase in the amount of xanthoprotein and indican in the serum. On the other hand a mere increase in blood nitrogen in benign sclerosis does not at all signify that malignant sclerosis has developed, save of course when there is also an increase in the two aromatic substances above mentioned. The author disagrees with those who see in the increase of the serum aromatics the cause of hypertension, but on the other hand increase of aromatics might conceiv-' --- medizinably ische

# LEGAL

# HABIT FORMING DRUGS-STATE STATUTES ANALYZED

By Lorenz J. Brosnan, Esq. Counsel, Medical Society of the State of New York

We have been asked by a number of physicians to set forth the present statutes relating to habit-forming drugs, and specifically to set forth the various statutes dealing with the unlawful possession or use of a hypodermic needle or syringe.

The present state statute dealing with habitforming drugs is Article XXII of the Public Health Law, and embraces Sections 420 to 445 of that Article. This Article is known as the Narcoue Drug Control Law.

By Section 421, the term "habit-forming drugs" is defined as meaning coca leaves, option, cannabis indica or cannabis sativa. The various ingredients herein enumerated are defined as follows:

'Coca leaves' includes coca leaves, cocaine, or any compound, manufacture, salt, derivative or preparation thereof, including alpha or beta eucaine, or any of their salts or any synthetic substitute of any of them, identical in chemical composition, but shall not include decocanized coca leaves, or preparations made therefrom or other preparations of coca leaves which do not contain cocaine.

"'Opium' (includes opium, morphine, codeine, diacetylmorphine heroin) or any compound, manufacture, salt, derivative or preparation of any of them or any synthetic substitute of any of them identical in chemical composition, but not apomorphine and its salts.

"'Cannabis indica' or 'cannabis sativa' shall include any compound, manufacture, salt, derivative or preparation thereof and any synthetic substitute of any of them identical in chemical composition."

Section 422 of the Public Health Law provides:

"Any unauthorized possession, control over, sale, distribution, prescribing, administering or dispensing of habit-forming drugs is hereby declared to be dangerous to the public health, and a menace to the public welfare."

The sale of habit-forming drugs on written orders may be made by a manufacturer, whole-saler, or apothecary, as provided by Section 424 of the Public Health Law, to any of the following persons:

"a. To a manufacturer, wholesaler or apothecary,

"b. To a physician, dentist or veterinarian.

"c. To a public or private hospital,

"d. To a hospital or institution licensed for the treatment of drug addiction.

"e. To a person in charge of a laboratory where habit-forming drugs are used for scientific or medical research, but only for use in such laboratory.

"f. To a person in the employ of the United States or of this state or of any political subdivision thereof purchasing or receiving the drug by reason of his official duties.

"g. To a captain or proper officer of a ship upon which no regular physician is employed for the actual medical needs of the officers and crew when not in port.

"Provided, however, that both parties to the transaction in each of the above cases are registered under the Harrison Act if required by such Act to be so registered."

It is further provided in Section 424 that the possession of or control over habit-forming drugs obtained as provided in this Section, shall be lawful only in the regular course of business, occupation, profession, employment, or duty of the possessor and in an amount necessary therefor. This Section does not apply to the supply of habit-forming drugs on prescription or administered or dispensed by a physician, dentist, or veterinarian.

The Section dealing with the professional use of habit-forming drugs is Section 426, which provides as follows:

"1. Veterinarians. A veterinarian may prescribe, administer or dispense, habit-forming drugs in good faith and in the course of his professional practice only, and not for use by a human being.

"2. Dentists. A dentist, in good faith and in the course of his professional practice only, may administer or dispense habit-forming drugs to patients under his immediate treatment.

"3. Physicians. A physician in good faith and in the course of his professional practice only, may prescribe, administer, or dispense habit-forming drugs.

"4. Nurses. A nurse, in good faith and in the course of her professional practice only, and acting under the direction or supervision of a physician may possess and administer habit-forming drugs. Any unused habit-forming drugs left by a physician with a nurse to be administered during his absence, upon dis charge of the nurse must be returned to the physician"

And Section 428 provides that physicians, dentists and veterinarians shall keep a record of all habit forming drugs administered or dispensed by them, showing the amount administered or dispensed, except such as may be administered or dispensed to a patient upon whom they shall personally attend Section 432 provides that before any habit forming drug is prescribed, administered or dispensed by a physician, he must make a physical examination of the person for whom the drug is intended

We now pass to the subject of the possession of instruments for the injection of habit-forming drugs. The statute governing the possession of instruments for the injection of habit-forming drugs is Section 433 of the Public Health Law, which provides as follows

"No person except a manufacturer or a wholesale or retail dealer in surgical instruments, apothecary, physician, dentist veteri narian, nurse or interne shall at any time have or possess a hypodermic syringe or needle or any instrument or implement adapted for the use of habit forming drugs by subcutaneous injections and which is possessed for the purpose of administering hibit forming drugs in less such possession be authorized by the certificate of a physician issued within the period of one year prior thereto."

From a reading of this Section, it will be noted that in order to constitute an unlawful possession of an instrument or implement for the injection of libit-forming drugs by a per-

son not in the excepted class of the statute, and who has not obtained within a period of one year prior thereto a certificate from a physician authorizing the possession of such instrument, two things must exist. First, the person must have or possess a hypodermic syringe or needle, or some instrument or implement adapted for the use of habit forming drugs by subcutaneous injections, and secondly the syringe, needle or implement must be possessed for the purpose of administering habit forming drugs. This Section was added by the Laws of 1927, Chapter 672 and became a law April 5th, 1927.

A violation of the above Section is a mis demeanor under Section 1751 of the Penal Law, and is punishable by a fine of \$500 or imprisonment not exceeding one year, or both such fine and imprisonment

There is a similar prohibition against the possession of instruments for the injection of habit forming drugs in the Sanitary Code of the Department of Health of the City of New York (Section 135)

There does not appear to be any reported case in either the Court of Appeals or the Appellate Division construing the Section with respect to the unlawful possession of instruments for the injection of hight forming drugs but it seems clear from a reading of the statute that, in order to constitute a violation of that Section even where the possessor did not have a certificate from a physicini issued within a period of one year, it would be necessary to establish that the possessor had the instrument for the purpose of administering habit forming drugs

## CLAIMED NEGLIGENCE IN CAESARIAN SECTION, RESULTING IN DEATH

In this case plaintiff s deceased consulted the defendant-physician, griving a history of five months pregnancy. The woman was thirty-two years old and a primipara. Arrangements were made with the defendant for the purpose of rendering prenatal care and also for the delivery.

The patient called to see the defendant-physician for examinations and prenatal care for the balance of the period of gestation, and until such time as the physician was advised that the plaintiff had been admitted to the hospital agreed upon and was in labor. The defendant-physician immediately proceeded to the hospital, where upon examination he advised both the patient and her husband that the patient could not have a normal delivery and would require a Cæstrin section. This was due to a contracted pelvis. Both the patient

tient and the husband agreed and approximately seven hours after her admission to the lospital a Cæsarian section was performed upon the patient. A living child was delivered the after-birth removed and the abdomen closed with all due and proper aseptic measures. Shortly after coming out of the anæsthetic, the patient's heart failed to function properly and the patient began to run a temperature. This continued for slightly more than forty-eight hours, when the patient died

Thereafter an action was commenced against the defendant physician for claimed negligence resulting in the death of his patient. The plaintiff, however, failed to serve a complaint after the commencement of the suit and in due course the action was dismissed for the plaintiff's failure to prosecute the same, thus ter minimizing the proceeding in the doctor's favor

# **NEWS NOTES**

# REPORT OF THE SECOND DISTRICT BRANCH

To the House of Delegates:

Gentlemen:

This populous Branch, numbering 2,773 members, comprises the very active County Societies of Kings, Queens, Nassau and Suffolk. We furnish about 22 per cent of New York State Society revenue from dues and have 35 votes in

the House of Delegates.

In Queens the outstanding feature of the year is the perfectly appointed new building at Forest Hills on Queens Boulevard which is now the home of the County Society. Since meeting in this new building attendance at regular Society meetings has increased one hundred per cent. Every member of the State Society should visit this building and in appreciating the accomplishment visualize what can be done materially anywhere if the profession is united and capably led.

Another activity worthy of note in Queens County during the year has been the cooperation with the Departments of Health and Education and the Queens Borough Tuberculosis and Health Association in the campaign for the physical examination of the pre-school child by the private physician. Queens claims to lead all New York City Boroughs thus far in accomplishing this end. Queens County Society regards this as a very important move, tending to provide preventive measures for children who would otherwise be neglected, while definite financial benefit accrues to the physicians of the County. Other activities in conjunction with the Queens Borough Tuberculosis and Health Association have been the educational campaigns for the prevention and control of heart disease, and two courses for physicians have been conducted. The Society has made a personal survey of Out-Patient Clinics and finds that the majority of the sick poor are obliged to seek medical care in the institutions of Manhattan and Brooklyn. Definite accomplishment along this line is expected early. A new general hospital of four hundred beds is now promised for Queens. Diphtheria immunization has been accomplished up to about 50 per cent of all school children.

Members of the Society have recently incorporated a society organized to do certain business for members, especially the collection of

delinquent accounts.

From these and other activities that have not been mentioned, it will be found that Queens County Society is thoroughly alive and growing more vigorous.

In Nassau County large things have been accomplished by the County Society along the lines of diphtheria immunization and the examination of the pre-school child. This Society has proven the private physician can be interested in public health projects and when so interested can contribute service and assistance which are extremely difficult to secure from other sources. President L. A. Newman, in his recent address before the Branch Meeting, uttered this pregnant sentence: "To all this might be added two observations; first, that from a dollars and cents standpoint it is cheaper to conduct public health campaigns through the organized physicians, and second, that it is possible for the physicians to contribute to the success of such campaigns without pauperizing the public and without a sacrifice of the economic rights of the profession." These facts have been kept so clearly in mind in the County of Nassau that it has become more or less automatic with lay organizations to think of the County Medical Society when they are faced with problems which concern medicine in any way. The first order of business for the present year is to secure a public hospital for chronic and incurable cases, venereal diseases, and to solve the acute and perplexing problem of com-municable disease. It is hoped and expected that this matter will be submitted to the voters at the next general election.

In Suffolk County the social and educational activities are largely left to the local districts especially those where hospitals are located. Suffolk County Medical Society, therefore, undertakes to assume leadership in Civic medicine along those lines which effect the entire County. special interests of the Suffolk County Society have been Tuberculosis and the County Health "The interest of the Society in Department. tuberculosis began in the year 1912 when it started a campaign for the establishment of a County Tuberculosis Sanatorium. It attained its goal in 1916, but climbing the mountain and attaining its summit was only the beginning of the tuberculosis work of the County Society. There followed ten years of development of the antituberculosis work and its extension to every section of the county by means of clinics, visiting nurses, and the practice of physicians. All the work was unified under Dr. Edwin P. Kolb, Superintendent of the Tuberculosis Sanatorium, who handled it as a communicable disease problem, and sought to find contacts with known cases after the manner of searching for smallpox. Moreover, Dr. Kolb handled his work in

a peculiarly friendly manner and secured and held the active good will of every doctor in the County. The results have been that the doctors of Suffolk County think in terms of tuberculosis and are in hearty cooperation with Dr. Kolb and the visiting nurses. The unifying system is entirely managed from a medical point of view. Thus the County Medical Society has had a definite object in view over a long period of years beginning with 1912 through a four-year campaign, ending in 1916, and a decade of development which is still far from being completed.

"The Suffolk County Medical Society began to discuss a County Health Department in the year 1926 and instituted a campaign which resulted in the establishment of the County Department This was another mountain top of progress attained, but like that of tuberculosis there still remains the process of development and popularization of the work. Its eighteen months of existence have been devoted largely to the investigations of health conditions in every part of the county, and in the development of organizations to meet the actual needs of the county. Just what the development of the County Health Department will be remains to be seen, but based on past experience it will have a natural growth and will be centered in practicing physicians just as tuberculosis work has been. One tangible result already has been the development of an interest in public health by officials of the County, towns and villages, to a degree which almost unsuspected when the Society instituted its campaign four years ago.'

Kings County:—The activities of the Public Health Committee have continued fostering relationship with the community and carrying out professional activities along public health lines. The second outstanding activity has been continuing and extending medical education of doctors of the Borough. The Society has actively cooperated with the Health Department in thre campaigns—health examination, diphtheria prevention and the cancer publicity. The new health work this year has been the undertaking of the health examination project in conjunction with the Brooklyn Boys Continuation School. The Friday afternoon lectures have been continued

and have attracted from four to six hundred physicians weekly. Longer and more constructive courses have been planned by the Joint Committee on Graduate Education and have been well attended. Medical education has been fostered by fifteen talks over the radio and one hundred addresses on subjects of lay interest given to clubs, schools and industrial groups. The Library has been used by 9,000 readers. Valuable foreign volumes were added to the library last year while the Librarian was in Europe. Milk certification has increased. During the past year the Society has established a Medical Information Bureau with the idea of caring first hand for many inquiries coming to us concerning physicians, methods of medical procedure, the work of institutions, advice regarding charlatanism and other matters. Thirteen hundred and fifty inquiries were received during 1929.

Thus it will be seen that in this populous district the County Medical Societies are endeavoring to make progress. One of the great tasks to be accomplished here is the enlistment of more of the member physicians in the army of those who would personally cooperate with the authorities and public to solve public health problems Your Branch Officers are especially interested in making the Second District's contribution to the work of the State Society larger and more helpful.

The Annual Meeting of the Branch was delayed until April 1st so as to stage it in the new building of the Medical Society of the County of Queens. The meeting was the largest in the memory of any one present. The program included superb reports from the Presidents of the component County Societies (leading features of which are included in this report) and splendid addresses by President-Elect Ross and Professor John O. Polak of Long Island College Hospital; Speaker Card, Secretary Dougherty, Treasurer Heyd, Editor Wightman and Ex-Presidents Kevin and Sadlier were guests of honor from the State Society.

Respectfully submitted,
CHARLES H. GOODRICH, President.
May 1, 1930.

# REPORT OF SPECIAL COMMITTEE TO CONSIDER THE POLLUTION OF THE NEW YORK STATE WATERWAYS, THE HUDSON RIVER AND ITS MAIN TRIBU-TARY THE MOHAWK RIVER

To the House of Delegates:

Gentlemen:

It will be recalled that this Committee was appointed by President Vander Veer as a result of the approval by you of the Dutchess-Putnam County Medical Society's resolutions at your last

meeting, June 3d, 1929.
After brief informal conferences your Committee met at Albany on October 14th, 1929, and resolved itself into a fact-finding commission. Its fact-finding was facilitated immeasurably by the wisdom of our President in appointing Dr. Edward II. Marsh, Secretary of the State Department of Health, as a member of the Committee, and by the earnest cooperation of Dr. Marsh and one of the Health Department Engineers, Mr. Earl Devendorf. These two gentlemen were able to answer all of the twenty questions which the Committee presented at our first meeting. In the discussion of that evening the tenor of the report of your Committee was determined.

Herewith follows a brief summary of the facts found:

- 1. Five (5) cities or towns obtain their water supply from the two rivers mentioned in the Res-The Mohawk supplies Cohoes. Hudson supplies Albany, Rensselaer, Catskill and Poughkeepsie.
- 2. In the fifteen years immediately past, waterbourne diseases have occurred in these municipalities as follows:

Cohoes—1927—48 cases of Typhoid Fever due to a crossed connection—since eliminated.

Albany—1924—140 cases of Typhoid Fever due to a crossed connection—since eliminated.

1927—30 cases—due to cross connection since eliminated.

Rensselaer-No outbreaks.

Catskill—1917—10 cases of Typhoid Fever. Poughkeepsie—No outbreaks.

3. Of these five cities and towns—Albany is building new water supply facilities (hill and mountain sources) so that in three years no more river water will be used.

Rensselaer—is planning a new source of supply and soon will be independent of river supply.

Catskill-has been ordered by the State Department of Health to secure supply from the hills, and will soon take no water from the

This will leave only Cohoes and Poughkeepsie dependent upon the rivers for water supply. The State Department of Health hopes and expects that these two cities will soon find their supply elsewhere, although this will be most difficult

for Poughkeepsie, (where there have been no outbreaks of water-bourne diseases during the last fifteen years).

- 4. Eighty-three (83) municipalities discharge sewage into the Mohawk and Hudson Rivers directly or through their tributaries. In most instances there is no other evident possible ultimate disposal.
- 5. To compel other equally safe means of sewage disposal would bankrupt any of the municipalities concerned if the expenses were imposed upon them, and would hopelessly bankrupt the State if the commonwealth should assume the
- Were all municipalities to deposit sewage elsewhere the rivers would still be unclean as drinking water resources as there would still be tugs, steamboats, barges, pleasure boats, fishing boats, picnic grounds and the like to contaminate
- 7. The State Health Department is insisting that all sewage systems which are now (and in recent years have been) connected with the rivers as outlet—have provisions for treatment so that no untreated sewage enters the rivers from these sources. This costs Five Dollars per capita for installation and between seventy-five and eighty cents per capita per year to operate. Other municipalities are being induced or compelled to put in treatment facilities as rapidly as their resources will permit. Thus a gradual evolution which will ultimately result in universal treatment has been instituted. With the above costs in mind we can see what a shock taxpayers would receive if any of the large cities were compelled to install adequate treatment in a short period of time-notably New York City.
- 8. Treatment is already completely in operation at Marcy State Hospital, in Rome, Frankfort, New Hartford, Dolgeville, Gloversville, Corinth, South Glens Falls, Albany, Bethlehem District, Ballston, Saratoga, Altamont, Pleasantville, Wappinger Falls and West Haverstraw.
- 9. In Schenectady 60% of sewage receives treatment.
- 10. There are definite plans for treatment or actual construction is under way at Whitesboro, Utica, Cohoes, Troy and Rensselaer.
- 11. Although the health records of cities using river water show an extremely low incidence or water-bourne diseases there is an annual improvement in the quality of sewage deposited in the streams.
- 12. The economic phase of the entire question cannot be disregarded. In any event, if we consider the State in its entirety, the cost of a very

few new water systems is negligible as compared with either universal treatment or diverting the sewage of eighty-three (83) municipalities (including New York City) elsewhere.

13. This economic question seems negligible compared with the practical difficulties of finding outlets for these eighty-three sewage systems

other than in the rivers.

14. The once-believed statement that ten miles of exposure of river water to sunshine and oxygen will render the water thereof free from nathogenic bacteria has been disproven.

15. The ordinary (and even extraordinary) amounts of chlorine used to sterilize suspected

waters do not endanger human kidneys.

In view of these facts your Committee rec-

1. That the Medical Society of the State of New York approves of the desire and plan of the State Department of Health to secure for all municipalities supplies of water from sources other than rivers.

2. That the Medical Society of the State of New York commends the activities of the State Department of Health aiming ultimately to secure universal treatment for all sewage deposited

in the rivers

3. That the Medical Society of the State of New York endeavor, through its membership, to acquaint the public with the facts above detailed and secure as far as is possible enthusiastic support of the principles "No river water for domestic purposes" and "No untreated sewage for the Mohawk and Hudson Rivers."

For all of these recommendations your Com-

mittee is unanimous.

Respectfully submitted,

CHARLES H. GOODRICH, Chairman

May 1, 1930

# REPORT OF COMMITTEE TO FORM A PLAN TO MAKE TOXIN ANTI-TOXIN AVAILABLE TO EVERY CHILD IN THE STATE

To the House of Delegates:

Four years of intensive activity by organized medical groups within our State Society—by lay organizations—by philanthropists and by State and County and City Health Departments have resulted in the administration of three doses of Toxin-anti-toxin to 818,770 children as reported to official agencies up to January 1, 1930, and in addition a very large number of immunizations have been completed by private physicians of which no record has been kept.

The case rate and death rate both in the State and in the City of New York have been cut in half during this period. A remarkable accomplishment which can again be duplicated by another 50 per cent cut in a very short time if practical plans can be developed for the immunization of every child entering school and for the immunization of as many children as possible at the end of their first year.

A continuous flow of education must be maintained to develop a health conscious citizenry which will revolt against any official or private neglect which may endanger the lives of children.

The following State Health Department figures for the past nine years speak for themselves and need no interpretation to this House.

Diphtheria Cases and Deaths in New York State (Outside of New York City) For Past Nine Years

				1930
				27.7 36

Reported diphtheria cases: 195 131 130
Reported diphtheria deaths: 17 20 14

THE 1930 DIPHTHERIA TREND INDICATES:

 A marked reduction thus far in cases: For the first three months of 1930 cases have been less than 200 each month, the first time this has occurred at this season of the year, and are the lowest yet recorded for these months.

The 131 cases for February and 130 cases for March are the lowest yet recorded for any one month with the exception of 128 in September, 1929, and 109 in September, 1928.

The total for the first three months of 1930 of 356 cases is 207 fewer than the number reported for the same period in 1929, 669 under 1928 and 750 less than 1927.

2. The fatality rate is much higher, as the deaths for the first two months of 1930 are the same as for this period in 1929, although the cases have been substantially reduced.

The fourteen deaths reported in March constitute the lowest number of deaths from diphtheria ever reported in that month.

Active campaigns with clinics are now under way in Buffalo, Amsterdam, Cohoes, Endicott, Elmira, Chautauqua County, including Jamestown, Dunkirk and Westfield, also in Medina, Saratoga Springs, Gloversville, Watertown, Oswego, Lackawanna, Tonawanda, Chicktowaga, Binghamton, Johnson City, Albany, Troy, Watervliet Cattaraugus County and Olean, Little Falls, Herkimer, Ilion, Mohawk, Frankfort and Poughkeepsie where the city has appropriated \$1,000.00 for the campaign.

Many smaller localities throughout the State are actively at work. The newly organized Cortland County Health Department is making Diphtheria prevention one of its chief 1930 objectives.

The Nassau County Medical Society is working hard with fine publicity—Suffolk County Health Department works steadily. Newburgh and Middletown are doing excellent follow-up work with splendid results.

The campaign in the five counties included in the City of New York is making wonderful strides under the inspiring leadership of Commissioner Wynne, a member of our Committee.

Up state and down state are working together as they should, and the following New York City

report is of the utmost significance.

The Diphtheria Prevention Commission reports a reduction of 56 per cent in the deaths from diphtheria and a 53 per cent reduction in the number of cases during the first quarter of 1930 as compared with the first quarter average for the previous six years.

For the first time in six years, cases of diphtheria dropped below the 1,800 mark during the first quarter of 1930 when they fell to 1,375. The average for the first quarter for the last six years was 2,931 cases. Comparing the first quarter of 1930 with that of 1929, we find 170 deaths in 1929 as against 82 deaths in 1930, and 2,800 cases last year as against 1,375 cases this year.

other words, diphtheria deaths and cases during the first quarter of 1930 have been cut just about in half as compared with the same period for 1929.

The figures for the last six years, covering only the first quarter, tell what is regarded as one of the most interesting experiences in the history of the Department of Health in its battle against While summer complaint among childisease. dren was overcome by the introduction of pasteurized milk, smallpox subdued by the enforcement of vaccination and typhoid fever virtually wiped out by the chlorination of the city's water supply, the attack on diphtheria was perhaps the first real direct frontal movement made on a common malady.

# 1929 Statistics

Inasmuch as the protective powers of toxinantitoxin administered to children in the first quarter of 1929 were not fully developed until the third quarter, and those administered in the second quarter not fully effective until the fourth quarter (to say nothing of those children immunized in the third and fourth quarters from whom results could not be ascertained until 1930) —we believe the effects of the campaign actually became successfully manifest in the final two quarters of 1929, and that the great saving of life, as well as the reduction in the number of new cases may rightfully be attributed to toxinantitoxin immunization.

New York City's diphtheria death rate for 1929 was 7.63 per 100,000 population, a reduction of 3.04 over that for 1928. Whereas there were 10,776 cases of diphtheria and 642 deaths from this cause in 1928, the year 1929 records 8,548 cases and 463 deaths—a decrease of 2,228 cases and 179 deaths.

The 463 deaths occurring in 1929 were among the following age groups:

Under 1 year  From 1 — 2 years  From 2 — 3 years  From 3 — 4 years  From 4 — 5 years	75 65 54
Total Under Five	146 19

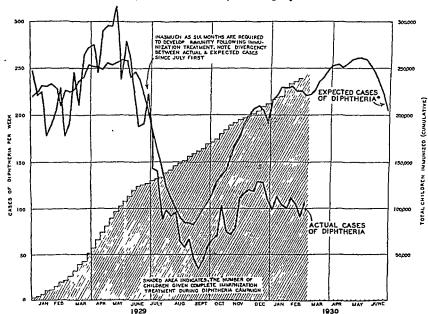

It will be seen from the foregoing that while we must endeavor to have all children under ten years of age immunized against diphtheria, we must concentrate our efforts upon the pre-school child particularly.

During 1929-211,985 children were immunized with toxin-antitoxin as compared with approximately 50,000 immunized in 1928.

Of the 211,985 children immunized:

### INFLUENCE OF IMMUNIZATION ON DIPHTHERIA PREVALENCE

Cases of Diphtheria reported in New York City each week, 1929 30, compared with the number expected, based on the previous eight years.

Prepared for Diphtheria Prevention Commission by Bureau of Health Education, N Y C Dept of Health

\*Diphtheria case expectancy for New York City es timated by the U S P H S on the basis of the number of cases for the previous eight years

92,549 were immunized in the Baby Health Stations:

56.853 in the schools-and

62,583—more than 30% of all children immunized—were taken to family doctors.

That toxin-antitoxin does pay and that it has paid well in the City of New York can be no better illustrated than in the accompanying graphic presentation of actual cases of diphtheria in New York City for 1929-1930, and expected cases that period according to U. S. Public Health Service figures

Your Committee recommends that this House of Delegates request the cooperation of the Departments of Health and Eduçation and of Health and Education officials of every county, city, town or village or district of the state, in a continuous campaign of education to reach those responsible for the pre-school as well as the child of school age.

Your Committee believes that the filing of every birth certificate should be answered by a letter to the parents—which should advise them to take their babies to their family physician for instruction in disease prevention—for vaccination against small pox and for immunization against diphtheria.

Respectfully submitted,

NATHAN B VAN ETTEN, Chanman April 1, 1930

#### REPORT OF THE COMMITTEE TO STUDY THE NURSE PROBLEM

To the House of Delegates:

Gentlemen:

Your Committee has continued the study of the nurse problem with an increasing conviction that satisfactory solutions are still remote.

The data disclosed by the researches of the Committee on the Grading of Nursing Schools have established the status of supply and demand, of economics, of education and of distribution.

Your Committee believes that when these studies, shall have been finished next year, there will have been erected a body of facts upon which remedial measures may be constructed.

We now know that there are in the United States 2,205 schools of nursing—that 25,300 nurses were graduated in 1929—that there is one graduate nurse in the United States to every 590 people—that there is one to 500 in the State of New York—one to 234 in the County of New York—that the average nursing life of a graduate nurse is 17 years—that except in localities where epidemics prevailed nurses had less employment in 1929 than in any other year—that many nurses come into the State of New York from Canada competing with nurses who are citizens of the United States, thus invading the already over-crowded field of our graduate nurses.

The general nursing field is further filled beyond the saturation point, indicated by the foregoing figures, by the large number of undergraduate and practical nurses who furnish little or no financial relief to the sick patient because they demand practically the same fees as graduates.

Apparently the only place where a shortage may be claimed is in the upper levels occupied by hospital superintendents or heads of training schools, or those qualified for teaching or those trained in the specialties.

Members of your Committee met with the

Board of Regents and with the Committee on Higher Education and secured the adoption of the new standards for admission to training schools which require two years of High School in 1930, three years in 1931 and four years in 1932.

The curriculum was also discussed—the Regents Committee approving the "Syllabus of Obstetric Lectures" prepared by Dr. Kosmak of our Committee and asking for further help in building a new curriculum.

Dr. Kosmak also has been appointed chairman of a sub-committee of the "White House Conference" to study obstetric nursing—a most important special study in view of our very sad maternal mortality statistics.

Your Committee regrets that the Nurse Registry law is apparently not being enforced and suggests that this House request the Department of Education to stimulate the license bureaus to observance of this law.

Your Committee recommends that the student entering a school of nursing should be of sufficient maturity—at least eighteen years of age—that she should present a certificate of complete health examination from a physician known to the school, that she should have character endorsements from at least two reputable persons, one of whom should be a physician, that she should be a native or a citizen of the United States, that no hospital should conduct a training school of nursing where the daily average of patients is less than twenty with affiliation, or less than fifty patients without affiliation.

Your Committee again recommends group nursing in hospitals, part time or hourly nursing in homes, and liberal support of visiting nursing organizations in their devoted service to the poor.

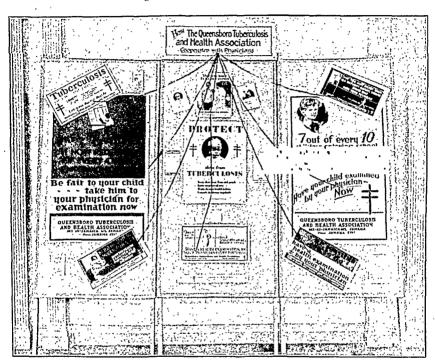

Respectfully submitted,

NATHAN B. VAN ETTEN, Chairman. April 1, 1930.

#### QUEENSBORO TUBERCULOSIS ASSOCIATION

The Queensboro Tuberculosis and Public Health Association works in close harmony with the Queens County Medical Society. How the two organizations cooperate is told in an exhibit shown at the meeting of the Second

District Branch of the Medical Society of the State of New York on April first in the new building of the Queens County Medical Society. A photograph of the exhibit is here reproduced.

#### **QUEENS COUNTY**

A stated meeting of the Medical Society of the County of Queens was held in the auditorium of the Society Building on March 25, 1930, at 8:30 P.M., President E. A. Flemming, M.D., in the chair, and 120 members present.

The secretary reported that the Comitia Minora meeting on March 8 had acted favorably upon a communication from the Legislative Committee of the Medical Society of the County of New York indicating a proposed amendment to the local laws of the City of New York for the year 1929 in relation to establishing a Department of Hospitals and defining its jurisdiction, powers and duties. The proposed amendment consisted of the in-

sertion in Section 692E which stated:—"The members of a medical staff or board shall serve without compensation," the addition:—"Except that where treatment is rendered to patients for which compensation is provided for under the Workmen's Compensation Act of the State of New York, the physician or surgeon rendering the medical and surgical services shall be entitled to receive such compensation." On motion, duly made and seconded, the Comitia Minora unanimously approved and endorsed this proposed amendment.

Two thousand dollars were appropriated for the conduct of the Business Bureau at the meeting of the Society on January 28, 1930, to be set aside by the Treasurer as a separate fund subject to the use of the Directors of the Business Bureau.

The matter of opening the library to the lay public was considered and on motion referred to the Committee on Library to report back to the Comitia Minora.

Dr. Boettiger for the Committee on Public Health and Public Relations requested the cooperation of the Society in the matter of more efficient blood transfusion service, an information booklet by the Welfare Council of New York, and the investigation by the New York Academy of Medicine on the problem of maternal mortality in the city, and supplied matter covering these subjects for publication in the Bulletin.

"The Membership Committee reported that it has assigned to the individual members of the Committee recent graduate physicians in their respective localities to canvass for membership. It also suggested that white buttons be secured bearing the names of the various members to be sold at a low cost and to be worn at the meetings to stimulate the spirit of the organization.

"Dr. H. P. Mencken presented the contemplated program for the Graduate Education.

The following new members were received: Albert J. Aptaker, M.D., 9440 210th Street, Hollis; Dallas G. Bray. M.D., 3048 36th Street, Long Island City; George V. Duffy, M.D., 8848 212th Place, Queens Village; Harry Clifford Oard, M.D., 150-84 87th Avenue, Jamaica.

The following were received by transfer: Abraham Braunstein, M.D., 2906 31st Avenue, Astoria, from the Medical Society of the County of New York; B. Shapiro, M.D., 9508 Polk Avenue, Jackson Heights, from the Medical Society, County of Sullivan, Liberty, N. Y.

Dr. Boettiger called attention to the new schedule of the consultation chest clinics of the Queensboro Tuberculosis and Health Association for the examination of cases of tuberculosis referred by physicians. He stated that a complete report is made to the physician referring each case, and that all intimate household, social, and industrial conduct of each positive case are examined and included in such report. The clinics are held in four hospitals in the borough. The schedule is available upon request—phone Jamaica 2557. He further spoke of a special educational campaign for the detection of tuberculosis among children conducted by the Association with a view of acquainting the public with a condition found in childhood which is the precursor of tuberculosis in the adult; and urging that children be taken to their family physician for examination.

Dr. F. G. Riley addressed the Society on the coming Friday afternoon talk by Dr. Clyde W. Collings, "Genito-Urinary Conditions," and urged the attendance by the membership of the Society. He thereupon offered the following resolution:

WHEREAS, it has been called to the attention of the membership of the Medical Society of the County of Queens that there are at the present time many practitioners of medicine within the city of New York who are advertising in an unethical manner in the daily press and other publications, and

WHEREAS, such practitioners are a menace to the public health, be it therefore

RESOLVED, that the Medical Society of the County of Queens go on record as opposed to such methods and that the Society give its support to any and all measures the Commissioner of Health of the City of New York may see fit to employ to eradicate such menace to the public health, and be it further

RESOLVED, that a copy of this resolution be sent to the Commissioner of Health, of the City of New York.

On motion, duly seconded and passed this

resolution was unanimously adopted.

The Chairman directed the attention of the members to the coming meeting of the Second District Branch of the Medical Society of the State of New York and urged the attendance of the members of Queens.

The following scientific program was presented:

1. Paper, "Coronary Thrombosis and the Causes of 'Angina Pectoris,'" by E. Libman, M.D., Clinical Professor of Medicine, Columbia University.

2. Paper, "Stagnation Thrombosis Occurring in Cardiac Disease," by Arthur J. Fischl, M.D.

3. Discussion by Drs. E. M. McLave, Joseph Baum and closed by Drs. Libman and Fischle.

4. Paper, "Pneumonia in Children," by Roger H. Dennett, M.D., Professor of Pediatrics and Director of the Department, New York Post-Graduate Medical School and Hospital.

5. Discussion by Drs. A. S. Tepper, Margaret Reynolds, E. L. Friedman, J. M. Dobbins, T. C. Chalmers and closed by Dr. Bennett.

E. E. Smith, M.D., Secretary.

#### BRONX COUNTY

A regular meeting of the Bronx County Medi cal Society, held at Concourse Plaza, on April 16, 1930, was called to order at 9 PM, the President, Dr Aranow, in the Chair

New members elected were Drs David I Bissett, Angelo R Cantelmo Joseph Erdman, Joseph O Fisher, Hilda M Iserlis, Peter T Panaro and Elvira Willis

Dr Magid, Chairman of the Committee on Medical Economics, submitted the Report of the Committee relative to a conference on the matter of permitting the Medical and Surgical Staffs of City Hospitals to charge for their services in compensation cases, and also with regard to the aim of the Commissioner of Health to raise the

standard of medical practice

Dr Aranow, Chairman of the State Legislative Committee, reported on the Legislative session just closed with regard to the Bills affecting the Medical Profession All the Bills introduced during the session which were objectionable and opposed by the Medical Profession, such as the Anti vivisection, Osteopath, Optometrist, Physio Therapist and Chiropractic Bills, were defeated On the other hand, all our own Bills, such as the Bill providing for the free choice of physician, and the Bill which would create a Medical Council in the Department of Labor, were defeated Dr Aranow stated that the Medical Profession should do a great deal more than it is doing in opposition to the cults. We ought to appeal to the colleges and to the scientific organizations If chiropractic has some scientific basis for it, then the colleges ought to teach it On the other hand, if, as we know, it is a fraud, then the colleges ought to help us fight these cults for the good of the people

The Secretary read the report of the Nominating Committee presenting the list of candidates designated by the Committee for Officers

and Delegates for the year 1930 1931

Under New Business, Amendments to the By-Laws were proposed These Amendments will be printed in The Bulletin and acted upon at the May meeting

The following resolutions were presented by the Bronx Gynecological and Obstetrical Society, through its Executive Committee for adoption by our Society

Whereas, A Report of the maternal and neo natal mortality has been published by the State Department of Health.

"Whereas, This Report has failed to disclose the necessary information which would be of help in reducing this mortality,

"Whereas, The Bronx Gynecological and Ob stetrical Society has voted to take up the study of the causes in the County of the Bron,

"Whereas, The membership of the Bronx Gynecological and Obstetrical Society is composed of members of the Bronx County Medical Society.

"Whereas. The Executive Committee of the Bronx Gynecological and Obstetrical Society has decided that it would be beneficial to enlist the cooperation of the Bronx County Medical Society

"Be It Resolved, That the Bronx County Medical Society go on record as favoring and sponsoring the work of the Bronx Gynecological and Obstetrical Society in this study '

It was moved and carried that the above Reso lutions be adopted

The Scientific Program then proceeded as fol Papers

1 The Frentment of Gonorrhea in Women,

Maurice O Magid 2 Pregnancy Complicating Fibroids of the Percy H Williams

3 Some Simple Procedures Which Make Ob stetrical Practice Safer and Easier

Benjamin P Watson

The Papers were then discussed by Drs Wil ham P Healy, Abraham J Rongy and Edward T Hull The discussion was closed by Drs Magid, Williams and Watson

I J LANDSMAN, MD Secretary

# THE DAILY PRESS

Old fashioned home treatments, as remembered by Briggs, whose cartoons are reproduced from the Herald Tribune of March 6 and March 11, 1930.

#### ANTIVIVISECTION

The New York Times of May 20 contains the following account of the activities of the antivivisectionists:—

"The International Conference for the Investigation of Vivisection, meeting at the Biltmore yesterday, sent a telegram to President Hoover protesting against alleged 'political' activities of certain departments of the government opposing antivivisection.

"'We do earnestly protest,' the message read, 'against the political activities of the United States Public Health Service and the United States Army in opposition to the bill to exempt dogs from vivisection in the District of Columbia now pending in Congress. We ask you to give this matter your serious consideration.'

"Another message to the President requested his aid in furthering the progress of

the bill, and a telegram to Senator Thomas H. Caraway of Arkansas asked him to investigate the 'political activities' of the two departments in opposition to the bill, adding that documentary evidence would be submitted in support of the request. A resolution asked the same Senator also to investigate documentary evidence to be submitted by the conference against the use of vivisection and serums.

"A telegram to Governor Ritchie of Maryland protested against the 'political activities of the Maryland State Board of Health' in opposition to the dog exemption bill, and asserted that more than 10,000 residents of Maryland desired the bill's passage by Congress. Another resolution endorsed a bill being introduced in Congress to provide for moral and humane education in the public schools of the District of Columbia."

#### NOISE ABATEMENT

The systematic campugn for abstement of unnecessary noise conducted by the Department of Health of New York City is bearing fruit. The New York Herald Tribune of Max

22 says editorially ---

"The Board of Aldermen has done a good turn for the people in adopting the ordinance to reduce the nuisance of the outdoor radio loud speaker. The measure introduced by Alderman Stand with the indorsement of the Noise Abatement Commission prohibits the doorway and window din from shops or else where except on special occasions such as events of national interest under police permit.

'In the volume of complaints about needless rackets the street radio hubbub has been a conspicuous target as perhips the most intrituting and gratuitous. As an advertisement it must very ten persons to one whom it pleases. But whether that is so or not it is unreasonable to inflict on the general public a high powered artificial disturbance of what hittle resemblance to quiet there is on the streets of the city. For their effort of silence one at least of the dispensable yawps of the current bedlam the aldermen deserve thanks."

The New York 1 mes of May 22 also says editorially —

"The Noise Abatement Commission is re-

ported to be pleased with the prompt action taken by the Board of Aldermen. The particular noise is one of those most complianed about. But it is doubtful if the relief will be so widespread as if further restrictions were placed on loud-speakers in open windows in private dwellings and apartments.

"In the Summer they do more to shatter the evening than anything except the clevated automobile trucks loud horns and the baby next door. It is to be hoped therefore that the ordinance will be extended—or another passed to supplement it—so as to give a measure of protection against the excessive use—or rather abuse—of radios in the home Perhaps a curfew law would be most effective Meanwhile a deafened public will be thankful for even the present measure of rehef."

The control of noise by a law court depends on evidence. When two or three neighbors complain that a noise is irritating and harmful, half a dozen others will swear truthfully that they enjoy that particular noise. The Noise Abatement Commission of the New York City Department of Health therefore in vestigated noises scientifically as reported on page 573 of the May 15th issue of this Journal Health officers and others interested in noise abatement will find the article valuable.

#### RELIABILITY OF TESTIMONY

The members of psychology classes in college have frequently been asked to write descriptions of incidents enacted before them at unexpected times and the result is always a wide variation in the accounts. The New York Times of May 20 describes one as follows.

"The reliability of witness testimony was again attacked by Dr Richard H Paynter, Professor of Social and Abnormal Psychology at Long Island University in announcing yesterday the results of the fourth of his series of experiments in applications of psychological technique to police administration and juris prudence

"The experiment was conducted with the aid of two students Afred Lucia and Charles M Rubin who had been coached to start a disturbance in the room during an examination period, and two fraternity brothers of Mr Lucia, who had been asked to intercede in his defense. A list of questions was submitted to the class by Professor Paynter immediately after the incident and again one week later. In the meantime the class had been informed.

that the episode had been staged as an experiment in psychology

"The results of this experiment clearly show the value of the study of difference between various individuals and in the same individual at different times. The wide divergences of statements from actual facts on all questions asked point to the subtle ways alterations go on in our intellects and personalities.

"There is found to be, among various mental activities, a degree of interweavings and interdependence surprising, not only in extent but also in our ignorance that such operations are taking place. Their evaluation is the work of

the psychologist

"Elusive preoccupations and preconceptions came into play and distorted the facts the individuals thought they saw and heard. Thinking, imagination, inventiveness actions and emotional disturbances operated in other ways to alter what was really seen and heard.

"No one is, of course, immune from being fooled, not even the psychologist. But training in psychology is of great aid in detecting and evaluating the multitudinous errors in the personal equations of observation."

### BOOK REVIEWS

OUINT Its Causes Pathology, and Treatment By CLAUD WOFTH F.R.C.S. Sixth Edition Octavo of 246 pages, illustrated Philadelplia P Blakiston's Son & Company, 1929 Cloth \$350

This classical work comes to the ophthalmologist in the same form as the earlier editions. The teachings of this pioneer have been so universally accepted that other teachings of equally sound principles are apt to be entirely overlooked. That an enormous material has been covered by this able worker is not to be demed but one is apt to forget that the more refined types of scientific studies were only carried out on a very small and select group Yet the data furnished by these was and select group Yet the data furnished by these was used to supply the actual proof of the existence of congenital and acquired varieties. To establish the pres ence of an amblyopia evanopsia it is necessary to demonence of an ambigonal examples it is necessary to demonstrate that the infant had normal visual acuity that the eye was unused for a prolonged period of time, and that the poor vision following, could not have developed from intercurrent disease or injury. Since congenital defects seldom come unaccompanied by other congenital defects it is to be expected that evidence will be presented of such conditions. The presence of such defects in other members of the same family would seem a necessary piece of evidence if we are to think of these amblyopias as congenital

It seems unfortunate that so classical a work should be so lacking in the more minute essentials which would have substantiated the theories set forth to the fullest extent Even the studies carried out have not in the judgment of the reviewer been set forth in sufficient

detail from a truly scientific standpoint

These features notwithstanding Squint will main tain its well deserved prominence on our bookshelves for many years to come JOHN N EVANS

On Prescribing Physical Treatment By Matthew B Ray DSO MD (Edin) Octavo of 179 pages, illustrated New York William Wood & Company 1929 Cloth, \$375

This little volume brings to us a very complete ac count of the uses and methods of hydrotherapy, and a briefer account of the other modalities of modern physiotherapy The details of hydrotherapy are well described in an interesting manner, with mention of the difference in technique as employed at the various bath resorts. The chapters devoted to electrotherapy and heliotherapy are complete though brief, and con tribute to make the volume of great value to the prac titioner who uses or prescribes physiotherapy

JEROME WEISS

DISEASES OF THE STOMACH A Text book for Practitioners and Students By Max Einhorn MD Seventh Revised Edition Octavo of 593 pages illustrated New York William Wood & Company, 1929

The ingenious methods of examination and treatment which Dr Einhorn invented early in the history of gastro enterology did more to establish it as a specialty than the efforts of any writer His book beside being wealth of practical points both to the general practitioner and the specialist. In these days when careful clinical observation so easily gives way to radiography and the laboratory his suggestions regarding history taking and the physical examination are invaluable

His liberal ideas concerning diet in health and disease bring one back to sainty when confused by the mul-tiplicity of complicated diet lists. He is concerned more with the principles of nutrition and the physical nature of food than with chemical composition and combinations The discussion of pathological conditions of the stom

ach presents a basic knowledge of pathology which most text books lack. The treatments in each condition is detailed and especially helpful having been tested

by many years of successful practice
In the archives of gastro enterology no name appears more frequently than that or Einhorn and it is re markable that one man should have the energy of mind to produce so much amid a busy practice, both in litera-ture and in useful inventions which have been accepted and proven of value to the stomach specialist

HENRY F KRAMER

THE PRACTICE OF REFRACTION BY W STEWART DUKE ELDER MA DSc. MD Octavo of 410 pages illus trated Philadelphia, P Blakiston's Son & Company, Cloth, \$100

This little book compares very favorably with similar American publications It is well arranged well illus trated and the descriptions are brief but clear

It has always been the reviewer's hope that a little more color would be added to works of this type by a historical sketch of each subject as it is taken up Such background always adds materially to the interest of

the most lifeless branch of ophthalmology An attempt to present normal and pathological conditions without an accompanying anatomical review makes

most difficult the necessary visualization

To a student of refraction the book will be useful as it follows well accepted practices and is modern in its application of recent data JOHN N EVANS

APPLIED ELECTROCARDIOGRAPHY An Introduction to Electrocardiography for Physicians and Students By AARON E PARSONNET, MD and ALBERT S HYMAN, AB MD Octavo of 206 pages illustrated, New York, The Macmillan Company 1929 Cloth \$400

The authors have attempted to write a book on electrocardiography for the clinician. They have well succeeded in their endeavor. They give a comprehensive view of the entire subject along modern lines and express it in simple lucid English.

There are no lengthy discussions on theoretical points which appears wise in view of the general plan to make the book a guide for the bedside practitioner rather than

the trained cardiologist

It deserves recognition and the reviewer wishes it every success C S DANZER.

DISEASES OF THE BLOOD BY PAUL W CLOUGH, M D 16mo of 310 pages New York and London Harper & Brothers 1929 Flexible leather, \$250 (Harper's Medical Monographs)

In this volume of a convenient size the essential fea tures of the diseases of the blood are presented. In the early chapters the blood cells normal and abnormal are described and a satisfactory description of the different diseases follows A logical classification of the anemias is offered based upon the pathogenesis. This is post nemorrangic anemia acute due to large amounts of blood lost and chronic from the continued loss of small amounts (2) destruction of blood within the body (hemolytic anemias) and (3) inadequate blood formation (aplastic anemias) A chapter deals with transfusion and another with the technique of blood transfusion is an excellent volume in every respect examinations. It is an excellent volume in every respect W L. McCollon

#### EXAMINATION OF SCHOOL CHILDREN IN WISCONSIN

The May issue of the Wisconsin Medical Journal describes a plan by which the examination of school children in Outagamie County, Wisconsin, is made under the auspices of the County Medical Society, under an appropriation of one thousand dollars by the City and two thousand by the County. The article reads:

"It was proposed that a minimum charge of \$3.00 per hour for the city and a charge of \$3.00 per hour with 50 cents mileage (each way) or \$1.00 (one way) would be most moderate and exceedingly fair.

"A panel consisting of all regular medical men in the county, irrespective of Society affiliations, was then made up who would do the work acting in two and threes and who would be called upon in regular rotation. The hours for such examination were arranged by the city school and county nurses, which would not conflict with the regular afternoon hours of the physicians. The work proceeded expeditiously and smoothly,—a most notable and almost unknown cooperation of all parties concerned.

"All defects such as (special eye, ear)

throat, neck, chest, skin and body were noted upon each individual card and such patient referred to the regular family physician for further attention. There were only two failures of medical men in reporting for duty and as no valid excuse was given, no further requests for examinations were made of them. As a result, a feeling of mutual confidence between the city and county authorities, laity and medical personnel has evolved itself.

"There is very little question of this work becoming an annual event. The parents, children, city and county authorities as well as the medical personnel are all intensely interested in the venture. Suggestions for the improvement of these examinations are always welcome. The examinations have been held in the various public (ward) schools in the city, and the district schools in the county.

"Finally supervision of the school child as regards his physical well being and thera-peutic prophylaxis for infection diseases is kept entirely in the province of the local medical man who should be competent to direct and carry on such work. More than

10,000 children were examined.

#### MAINE PUBLIC HEALTH ASSOCIATION

The April number of the Maine Medical Journal contains the following editorial on the Maine Public Health Association:

"Maine is living up to her motto, 'Dirigo,'

in public health affairs.

"The Maine Public Health Association is doing for the people of this state, with the advice and direction of the physicians of Maine, a work in the interests of health which is already a model for other states. By spreading the gospel of health, by educational campaigns, through clinics and lectures by reliable agents, this Association is carrying light into dark places, financing these measures for the most part by sums raised in the locations where the work is carried on. This is sound policy. The Maine Public Health Association deserves the whole-hearted support of the physicians and people of our state.

"Public health activities, if carried on in this way and properly supervised by the profes-

sion, should be an effective weapon with which to fight State Medicine. To the State belongs the safeguarding of our liberties. To the Medical Profession belongs the preservation of the Public Health.

"Some idea of the scope and variety of the public health work now carried on in our state may be gained by a study of the carefully prepared reports printed in this number of the Journal. One-third of the Board of Directors of this Association are medical men, which should guarantee adequate professional supervision, and control and secure the greatest good to the greatest number."

The finances of the Association are summed up by the financial Secretary as follows:

"We began in 1929 with all back bills paid, and cash on hand amounting to \$1,385.67. The first activity of the year was a checking up of the Christmas Health Seal and Bond Sale.

(Continued on page 678-adv. xvi)

# HAY FEVER

### An Advertising Statement

HAY FEVER, as it occurs throughout the United States, is actually perennial rather than seasonal, in character.

Because in the Southwest—Bermuda grass, for instance, continues to flower until December when the mountain cedar, of many victims, starts to shed its pollen in Northern Texas and so continues into February. At that time, elsewhere in the South, the oak, birch, pecan, hickory and other trees begin to contribute their respective quotas of atmospheric pollen.

But, nevertheless, hay fever in the Northern States at least, is in fact seasonal in character and of three types, viz.:

TREE HAY FEVER—March, April and May GRASS HAY FEVER—May, June and July WEED HAY FEVER — August to Frost

And this last, the late summer type, is usually the most serious and difficult to treat as partly due to the greater diversity of late summer pollens as regionally dispersed.

With the above before us, as to the several types of regional and seasonal hay fever, it is important to emphasize that Arlco-Pollen Extracts for diagnosise and treatment cover adequately and accurately all sections and all seasons—North, East, South and West.

FOR DIAGNOSIS each pollen is supplied in individual extract only.

FOR TREATMENT each pollen is supplied in individual treatment set.

ALSO FOR TREATMENT we have a few logically conceived and scientifically justified mixtures of biologically related and simultaneously pollinating plants. Hence, in these mixtures the several pollens are mutually helpful in building the desired group tolerance.

# EXAMINATION OF SCHOOL CHILDREN IN RHODE ISLAND

The following editorial from the May issue of the *Rhode Island Medical Journal* expresses a point of view which seems to be opposed to that of the physicians of New York and other States:

"We have at hand a newspaper clipping which purports to be a condensed résumé of the supervision and inspection of health in the public schools, in which some \$84,000.00 are spent on same during the last year. Together with this staggering announcement comes one none the less astonishing that 96% of public school children are under medical supervision. It does not state what portion of this 96% are under private and what under public supervision, but it may be inferred that a large portion of these are under State or what may be as well termed Charitable treatment. Let us for a few minutes consider what this means. In the first place, any such high percentage as that may suggest that the race is undergoing a retrograde metamorphosis which exceeds in extent anything ever thought, anticipated or believed. This, it must be borne in mind, is in early youth when the vital powers should be at their highest and fullest vigor and strength. Is it possible that they are born of diseased parents, illy nourished in infancy, and deprived of the usual necessity of food, light and air?

(Continued on page 685-adv. xxiii)

(Continued from page 684-adv 11111)

Had these figures been 50% or under, we should be astonished; but with 96% we are simply flattened out. Before we can discuss the question of pauperism we must know the proportion of these that are State charges and that percentage under private care, also the nature of the ailments. If as stated in the article, there is such enormous deterioration in the youth of today, it is time that the entire medical profession be aroused.

"Comes at this very time an able address by the retiring President of the Providence Medical Society on the subject of Medical Leadership or State Medicine. We have been interested to learn just what State Medicine is, but, whatever it is, the foregoing would appear a part of it, and an interested and insidious part, too. Our problem is not that of England, where there is a tremendous amount of destitution and a dole. But from a medical standpoint, ours is rapidly becoming a race of paupers, of well dressed and apparently prosperous persons without pride, who gladly receive what is more precious than alms, and who, if compelled to employ a physician, would not pay him and do not intend to pay for the necessities of life if they can avoid it.

free system is evidently encouraging this mendacity, and this system is aided and abetted by those who should be encouraging a sterner manhood and a more honest citizenship than is being developed at the present time."

#### COUNTY HEALTH COMMITTEE IN WISCONSIN

The organization for general public health work in Wisconsin is described in the Wisconsin Medical Journal of May as follows

"There is in every county in Wisconsin, a county health committee, consisting of the juvenile judge, the chairman of the county board, the county superintendent of schools, the deputy health officer, and a woman appointed by the county board. Its duties are to direct the work of the county nurse and supervise general public health and welfare work in the county. The local medical profession, which is most interested in and conversant with health conditions and problems in the community, is not and cannot be legally represented in this committee. However, a committee of the county medical society can meet with this board, in an advisory capacity, to their mutual benefit.

mention the JOURNAL when writing to advertisers

(Continued from page 685-adv. xxiii)

"Similar committees can be apointed to meet with health departments in larger cities. Where this has been tried the committees have been cordially welcomed by the county health boards and the health departments. Other similar points of contact should be sought and developed as occasions arise

"By these methods greater cooperation is secured by public health agencies from the medical men and their work can be carried on more efficiently; the public is saved from exploitation by sincere but over-realous health and welfare workers and the legitimate rights of individual physicians can be protected.

"The public will continue to look to the medical profession for leadership in health matters so long as that leadership is sincere, efficient, and fair to all concerned. At a time like this we must put forth every effort to continue to maintain this leadership and merit this confidence."

Another item in the same Journal states that the Medical Economics Committee of the State Society plans to try to secure an amendment of the law requiring the appointment of one or more physicians on each county Committee.

### GOLFING AT THE OHIO ANNUAL MEETING

The following abstracts from the half page announcement of a golfing tournament to be held in connection with the annual meeting of the Ohio State Medical Association are taken from the May issue of the Ohio State Medical Journal:

"A record-breaking entry list for the Tenth Annual Tournament of the Ohio State Medical Golfers' Association to be held at the Columbus Country Club, Monday, May 12, the day preceding the opening of the Eighty-Fourth Annual Meeting of the Ohio State Medical Association at the Neil House, Columbus, is predicted by Dr. Carl A. Hyer, Columbus, president of the golfers' association.

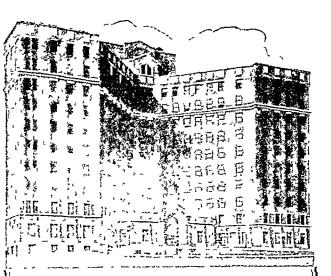

"If weather conditions are satisfactory, between 200 and 250 physicians from all parts of the state are expected to tee off in the meet which has become one of the unofficial but interesting and important features of the annual meeting of the State Association.

"The Columbus committee on arrangements, appointed Dr. Hyer, has been busy for several weeks assembling a list of approximately 35 attractive prizes and completing details.

"A majority of the past-champions of the golfers' association are planning to be on hand in an effort to dethrone Dr. J. L. McEvitt, Akron, who copped the championship last year at Cleveland.

"A program of special entertainment has been arranged for the annual banquet which will be held at the clubhouse in the evening

when the prizes will be awarded.

"The Columbus committee has arranged for transportation for visiting golfers, who do not drive to Columbus. Machines, provided by Columbus physicians, will visit the various Columbus hotels on the morning of the tournament to pick up golfers who have no other way to get to the course. The first foursome is scheduled to tee off as near 7:30 a.m. as possible

"Every member of the State Association who plays the game is urged by the officers and local committee men to take part in this year's meet with its unusually large prize list and which will be played over one of the finest courses in the state."

The May number of the Nebraska State

Medical Journal says:

"Golf is a game that makes a man who is too lazy to mow his lawn, work when he thinks he is playing."

An old definition of play is that it consists in working hard at something one likes to do.

## POPULAR MEDICAL EDUCATION IN WISCONSIN

The State Medical Society of Wisconsin prepares and distributes popular articles on medical education and contributes them to the newspapers. The issue of May contains one on "Dangerous Cosmetics" and one on "Mental Health." It also prints the following editorial copied from *The Capital Times*, Madison, of April 19, 1930, addressed to the State Medical Society

"Someone in your organization should be credited with doing all of us a lot of good through the publication of your bulletins exploding a lot of fancy and assorted fables about diseases. With health, probably the most concern to everyone, the possibilities for quackery, superstition and even downright fraud in this field are practically unlimited. In a recent issue of *The Capital Times* we see that you exploded that old tale about shingles encircling the body and causing death. We remember hearing that one a great many times and we hope your facts in the matter will clear up the fog in the minds of many who likewise heard the dire tale. We believe the

(Continued on page 689-adv. xxvii)

(Continued from page 688-adv. xxv1)

medical profession is taking a smart step in enlarging its publicity in projects similar to these bulletins. Distrust of some in your profession may have grown from their misunderstanding of your ultra-conservativeness in matters of publicity."

#### COMMISSION ON NEW TREATMENTS IN MICHIGAN

Not all medical men make good representatives in our State Legislatures, as is illustrated by the following editorial in the May issue of the Journal of the Michigan State Medical Society:

"There appeared in one of the Detroit newspapers a few weeks ago an announcement in the shape of what was evidently an advertisement to the effect that one of our State Representatives purposed introducing during the next session of the Michigan State Legislature a bill to create a 'State Medico-Legal Commission' which will be empowered to require that all news advances of treatment and methods in the field of medicine be submitted to the Commission by any licensed practitioner in Michigan who may originate or perfect any such new advance or method, and that it would be the duty of this Commission to investigate most rigidly and thoroughly the new advances and treatment methods and report to the people their findings. Then the article goes on to extol the merits of a method of treatment of a Detroit doctor. As the physician referred to in this announcement is not a member of the County or State Medical Society or the American Medical Association, we make no comment,

"For the information of the Representative, however, as well as of any others who may be doubtful, we wish to say that every new method proposed in medicine or surgery is thoroughly tried out and passed upon by those most competent to evaluate its merits; that this custom has been in vogue throughout the civilized world for almost a century; that the medical profession contains its own severest and sanest critics; that as soon as any method of treatment proves itself as being of real value, the people at large become the beneficiaries and that without delay. Therefore we fail to see what useful function any such commission as that suggested could perform. In this regard we quote the splendid sentiment expressed by Adams Gowan White: 'No scientific discovery is accepted until it has been checked again and again by investigators working with the most rigorous and vigorous skepticism. At the court of science every prisoner is suspected until proved innocent by a cloud of witnesses before an implacable bench of unemotional judges."

# DEXTRI-MALTOSE WITH VITAMIN B

IN 1922, the Mead Johnson Research Laboratory evolved a vitamin B concentrate. Realizing from our own constant research, and that reported by others in the scientific literature, the rapid changes going on in the understanding of the vitamin B complex, we refrained from marketing any vitamin B product until we could be absolutely assured of its potency and safety both experimentally (on rats, birds and other animals) and clinically (on babies).

Now that this time has arrived, we offer the medical profession, with confidence, DEXTRI-MALTOSE WITH VITAMIN B for use in all cases where the physician wishes to employ the well-known carbohydrate value of the Dextri-Maltose he has used successfully for so many years, and in addition the now accepted benefits of vitamin B—antineuritic, antipellagric, and appetite-and-growth stimulating. One gram of this product is equivalent in vitamin B<sub>1</sub> and vitamin B<sub>2</sub> potency to approximately .4 gram of dried yeast or .8 gram of wheat embryo.

There is no danger of intestinal irritation or other digestive upset from DEXTRI-MALTOSE WITH VITAMIN B—due to the fact that Mead Johnson & Company's experimenting is conducted before marketing. Samples and literature available to physicians.

# A Drugless Corrective in

# CONSTIPATION

ates that in chronic constipation, colitis, fissure and hemorrhoids, where gentle and regular evacuation is essential, laxatives not only fail to prove corrective, but often cause irritation.

Bland bulk and lubrication are now considered the important aids to a non-constipating diet, and for this reason interest has centered on the introduction of the plant seed of plantago psyllium, now available for use under the name

# Psylla

On coming in contact with water the small brown seeds swell and throw off a peculiar mucilaginous substance.

In the intestinal tract, therefore, Psylla provides both bland, non-irritating bulk and lubrication—a great aid in the treatment of constipation.

Where the condition is complicated by the presence of intestinal putrefaction and toxemia, the action of Psylla can be supplemented by the use of Lacto-Dextrin (Lactose, 73%—Dextrin, 25%)—a colon food which promotes the growth of the normal intestinal flora.

Let us send you a copy of the most recent literature on these accessory food products. We will also be glad to let you have free clinical samples for trial.

# A Dependable Agent For Supplying Calcium In Diffusible Form

KALAK WATER presents a saturated solution of calcium as the bicarbonate.

"Of the inorganic salts of calcium, the bicarbonate was the most effective in raising the blood calcium." (W. H. Jansen—Deut. Arch. f. klin Med. Oct. 1924.)

It is not possible to present calcium bicarbonate as a dry powder or as an effervescent mixture to be added to water. This salt can be maintained as the bicarbonate only in an aqueous solution that is charged with carbon dioxide.

KALAK WATER CO. 6 Church St. » New York City

# LITTLE HEART STRAIN

With This Method of Producing Non-Specific Fever

THE contious physician will naturally wish to know what effect, if any, Transkutan baths have on the heart. In

the accompanying curve is shown the in crease in the pulse during and after I rankutan baths. These data represent the mean of over 220 treatments. The increase shown is moderate and subsides regularly. It is the opinion of those familiar with the effects of these baths that there is no druger

of detrimental results even where there is considerable heart impairment

There are other factors which contribute to the safety of these baths when heart conditions must be reckoned with Becruse of the marked hyperemia produced in the skin, there is a distinct lowering of the blood pressure which, of course, lessens the load under which the heart acts. Moreover, the entire treatment being external, without any use of narcotics or depressants, the stimulus may be instantly removed at any moment indicated.

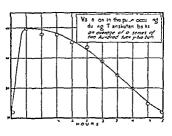

Because it acts by way of the skin it is apily called transcutaneous therapy, and the activating substance is called Transkutan Transkutan is supplied in three dosages, in convenient 5-ounce bottles, each sufficient for one treatment It is a scientific combination of a highly concentrated solution of natural mineral salts with turpentine, oil of wintergreen, menthol and camphor.

Transkutan is used in a hot both followed by a sweat pack and six to eight hours' rest. As may be seen from the

accompanying chart a moderate increase in the pulse rate is produced which slowly and regularly abates There is concomitantly a marked disphoresis and fre quently a leucocytosis

Transkutan baths havebeen provento be of the greatest value

as adjuncts in the treat ment of the diseases of the rheumatic group Arthritis especially, of virious categories, has yielded to the beneficial results of Transkutan baths Records are available of many long-established cases successfully treated Every physician has such cases Every physician should, therefore, investigate Transkutan All inquiries should be directed to the address below on your office stationery as Transkutan is sold only to the profession directly

TRANSKUTAN, Inc., 8 West 40th Street New York, N Y Gentlemen

Kindly send me, without obligation, full information on the use of Transkutan for the easy, pleasant, safe and controlled production of non specific fever

KALAK WATER CO. 6 Church St. » New York City

### FOR CHRONIC SLUGGISHNESS

Psyllium seeds of selected grade, in their natural state — clean and free from impurities — that's NATURALAX.

Naturalax is practically tasteless and has no disagreeable properties. The fact that it can be administered in a variety of ways is important "when treating patients whose delicate condition makes it imperative to avoid any form of treatment that may produce further irritation.

Naturalax is a demulcent and emollient, and can be used with safety when inflammatory infections are present. Naturalax is not habit-forming and treatments may be prolonged for any length of time. It is, therefore, an ideal regulator.

Naturalax is packed in two sizes only — 8 ounces and five pound tins. An original 8 oz. tin will be gladly sent free of charge to any physician upon request.

NATURALAX

LANMAN and KEMP, Inc. 135 Water Street, New York

Though less spectacular than the achievements of the engineer the fruits of research in the medical sciences are quite as essential to human welfare and progress.

Biological research has provided the means of combating the increased danger of infection by tetanus spores due to the multiplied wounds of industry, travel, and play.

The administration of Tetanus Antitoxin should be a routine treatment of all wounds liable to be infected with tetanus spores. In manifested tetanus the antitoxin gives better results than any other treatment.

TETANUS ANTITOXIN, LILLY, is purified and concentrated by methods which give remarkable clarity and limpidity, low total solids, and a material reduction in serum-sickness-producing constituents.

TETANUS, ANTITOXIN, LILLY, is supplied through the drug trade in syringe containers practically assembled ready for use:

A 39 1,500 units

A 47 10,000 units

A 38 1,500 units, in vials

#### PULSATING EXOPHTHALMOS\*

By ANTON S. SCHNEIDER, M.D., PLATTSBURG, N. Y.

In the presentation of this paper three points are stressed. First, the literature has been collected and reviewed; secondly, tying off the common carotid is emphasized as the method of choice in the cure of pulsating exophthalmos; and third, preservation of full vision in the case reported here in view of the length of time the injury has existed.

In 1809 pulsating exophthalmos was first described by Benjamin Travers but at that time the intimate connection betwen the internal carotid artery and the cavernous sinus was not recognized. Baron of France is due the credit of finding at post-mortem a rupture of the internal carotid artery in its passage thru the sinus. We know that there is a rupture or an aneurism of the internal carotid artery in its intra-cranial course thru the cavernous sinus.

An excellent review of the literature up to 1924 and a thorough analyses of the then reported 588 cases is given by C. E. Locke in the Annals of Surgery, Dr. Locke on May 15th of this year lost his life in the line of duty while helping those overcome by fumes at the Cleveland disaster. In this review the percentage of spontaneous and traumatic, of male and female, the end results, etc., are tabulated. Essentially the same percentages have been found in the literature up to the present time. The statistics show that spontaneous pulsating exophthalmos occurs more frequently in women than in men, the percentage of the traumatic type is higher in men, betwen the ages of 25 and 35.

When pulsating exophthalmos is considered from a mechanical point of view there is a sudden marked diminution of arterial blood at the time of rupture, to the opthalmic artery and to the half of the brain supplied, and a blocking off of the return flow through the ophthalmic veins and through the cavernous sinus to the internal jugular vein. There must of necessity be an engorgement by venous

blood of the parts affected, namely, retina, bulbar and lid conjunctivæ and the orbital veins. Due to this back pressure the alarming picture of proptosis, edema and dark bluish congestion of the eye appears and bruit is heard by the patient. Synchronous with the heart beat there is a pulsation of the eyeball, felt when the fingers are placed on the lids. These pulsations can be demonstrated by placing a strip of paper about 3 inches long over the eye ball. One end of this indicator is attached to the inner wall of the nose and the free end is seen to move up and down in rhythm with the heart beat.

Since the internal carotid artery supplies the half of the brain on that side many and diverse symptoms are manifested. These range from complete unconsciousness at the time of rupture to mild degrees of mental disturbances, and from complete hemiplegia to mild choreiform movements and paresthesiæ. The symptoms at the onset and their improvement later on are capable of mechanical explanation. Sudden anemia of the hemisphere results in complete cessation of the functions of the brain and when collateral circulation is established through the basilar artery and the Circle of Willis, improvement takes place. It seems but reasonable, in order to affect a cure of the symptoms that a process should be adopted which would shut off the arterial blood supply to the point of rupture, and this proximate to the bifurcation of the common carotid. In this way a condition similar to that at the onset is produced. True, in many cases, symptoms of hemiplegia and other signs appear but these are of short duration because the load already carried by the collateral circulation is temporarily increased and then reaches a level maintaining equilibrium. It does not seem good judgment to tie off the internal carotid alone, because of the increased supply through the external carotid. Neither does it seem wise to ligate the ophthalmic veins in the orbit because only

<sup>\*</sup>Read at the Annual Meeting of the Medical Society of the State of New York, at Utica, N. Y., June 5, 1929

the back flow is secured and not the source from which the blood is coming, and it is claimed, that interference with this back flow

causes glaucoma.

The various ways in which attempts have been made to cure the symptoms are, besides those mentioned, digital compression over a long period, ligation of both carotids, partial occlusion by means of a fascial band, or occlusion, in stages, with the Neff clamp, and gelatin injections. The serious results of loss

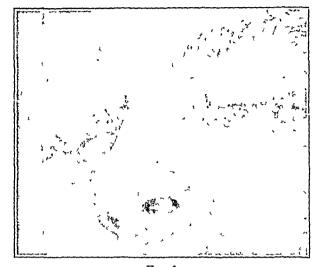

Fig 1
L M. Front view before operation.

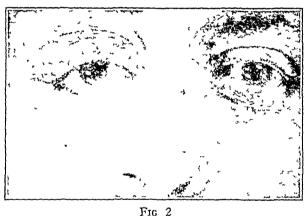

of vision, as reported in the literature, make it seem advisable to resort to the most efficient method in the shortest space of time.

Of the various methods used none have proved so consistently of benefit than tying the common carotid. The percentage is about 65 cures to 23 failures Spontaneous cures have been recorded in a few cases. Digital compression is reported as curing 23% and not affecting 73%. The ill effects which follow compression have been suggested as due to the pressure on the vagus nerve lying in the carotid sheath, as well as to the decreased blood supply to that part of the brain Ligation of the internal cartoid and opthalmic vein has been of benefit in some cases and cures by gelatin injections and even by installation of adrenalin have been reported.

Various factors determine the end result. The injury in 70% of the cases is a basal fracture which involves the sphenoid bone. This often leads to a direct injury to the optic nerve or compression of it by a blood clot or by cicatricial tissue. Depending on the type of injury and the duration, optic atrophy occurs to a greater or less degree. Pressure on the supra-orbital nerve by a blood clot causes pain. Collateral circulation may be quickly established or be very slow. Again it

is urged, that as soon as a definite diagnosis has been made and the patient is capable of withstanding the shock, ligation of the common carotid artery should be done.

L. M., male, age 35, was first seen March 8, 1929, and gave rather an indistinct history of a swelling 17 years ago in the right temporal region. No definite statement of an injury could be elicited, but he was operated upon at that time, the diagnosis being aneurism. The scar is plainly visible in the slides about to be shown. In 1925 there was some swelling again which persisted only for a short time. About a month ago, in February, he went swimming but did not remember whether he struck his head or not. Since that time there was a swelling of his lids and protiusion of the eyeballs, which gradually increased. He also stated that there was a gushing noise in his head which kept time with his heart beat At times he had difficulty because he saw two objects and it annoyed him. There was no pain.

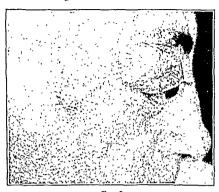

L. M. Front view, seventeen days after operation.

Physical Examination: Well developed and well nourished. Striking asymmetry of the face. the right side more prominent than the left There was a marked exophthalmos of the right cye, Hertel 30, left 19. The upper lid showed a mass of circoid vessels and to a slight degree on the outer side of the lower lid. The conjunctival vessels were full, cul-de-sac darkly congested Cornea clear, pupil 4.5 mm, regular, active to light. Vission 20/30 plus. The media were clear, disc clearly and distinctly outlined, with a heavily pigmented border The veins were about normal in size and the arterial walls were clear and distinct and showed no compression.

Left eye: Cornea clear, pupil 4.5 mm, regular, active to light, media clear, disc clear and distinct. very faintest pigmentation of the border and very slight increase in the size of the veins.

There was a distinct visible pulsation over an ovoid area starting from the inner canthus and extending well into the temporal region

1:16. 3

L. M. Side view, seventeen days after operation, also showing scar of previous operation for "ancurism."

back to the attachment of the auricle. On palpation there were forcible pulsations and on ausculation bruit over the entire right side

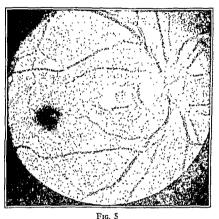

L. M. X-ray picture of right orbit showing mass, reported as "malignant growth."

and transmitted to the left, was heard. There was full motion of the globe except upwards where it was difficult to pass beyond the 25 point line. Compression over the carotid

stopped the bruit and the fundus was momentarily blanched. X-ray report was: On the right side there is a mass extending from the super-ciliary ridge downward involving the entire orbit, and also extending into the antrum. There is also a marked bone erosion involving the super-ciliary ridge and the adjacent portion of the parietal and temporal bones, evidently a malignant growth.

The disparity between the x-ray report and the clinical findings may be accounted for on the basis of the operation for aneurism 17 years ago. This can place the interpretation of the erosions as due to aneurism or to a

L. M. Photograph of fundus of right eye, negative.

cavernous hemangioma, rather than to a malignant new growth.

Wasserman, urine and blood examinations negative. General physical and neurological examination negative.

Operation. On March 12, 1929 the common carotid on the right side was securely ligated. Because of the danger of increased swelling and exposure of the cornea, two mattress sutures were placed through the lids. March 15th, marked improvement, all the vessels were smaller but the disc looked a trifle pale. March 21st arteries and veins certainly smaller, and faint pallor of the disc. March 24th, left the hospital and on March 29th vessels large; but there were no pulsations. Hertel at this time 28, left 10, and vision O. D. 20/20, and free motion of the globe in all directions. When last seen April 27th, the improvement had persisted. There is still some swelling but it is hoped this will gradually subside to normal.

#### NOISE—ITS MEASUREMENT, EFFECT AND CONTROL

By E. B. DENNIS, Jr., C.E., NEW YORK, N. Y.

From the Noise Abatement Commission of the Department of Health, New York City

→HE rather testy old gentleman who said, "Noise is anything that I don't want to hear," provided us with a definition that is not scientific, but which has the advantage of being broad and general enough to meet the requirements of a subject having many ramifications. There are many definitions of Noise in current use and most of them do not tell the whole story. In Webster we find that "Noise is a sound without agreeable or musical quality," while another authority states that "noise is sound produced by the irregular or unperiodical vibration of a body in the air." But curiously enough there are times when sounds that are decidedly musical become noise.

Early on a quiet summer evening a beautiful piano concerto played by the talented young lady next door may be very enjoyable, but the same concerto played by the same young lady in the same excellent manner at one-thirty A.M. when sleep is being wooed, would be termed noise in no uncertain manner. And yet the sounds generated each time had the same musical characteristics so far as structure of the sound waves is concerned. The rhythmical vibrations of a perfectly functioning motor may be musical sounds in the ears of the engineer in charge, and yet it is not difficult to conceive of some other person calling the same sounds noise. It is therefore apparent that the reaction of the individual enters into the determination and makes it very difficult if not impossible to classify as noises, as they are generally understood, those sounds which have, or do not have, certain characteristics of pitch or frequency, amplitude or intensity, quality, and frequency of occurrence. Something more must be considered and that is the annoyance effect

The data which have been collected by the Noise Abatement Commission of New York City indicate that the most annoying noises are those that the average person thinks are unnecessary or due to thoughtlessness on the part of the person responsible for them The replies to the questionnaire printed in the Metropolitan newspapers show quite clearly that the noise of the radio loudspeakers and automobile horns are annoying to a greater degree than the noise of the elevated or the subway, altho the actual intensity of the latter two noises is much greater than of the first two In other words, when an automobile horn is blown to call someone from the house. we know that it is because the person blowing

it is too lazy to get out and walk up to the door, and that he is entirely disregarding the peace and comfort of the neighborhood. The roar of the elevated may be most disturbing, but we realize that it is from a necessary form of transportation, and so we do not react so strongly. The more unnecessary we feel the noise is, the more angry we become and the more we abominate that particular source of annoyance.

The question of why noise is annoying and the equally important subject of the degree of annoyance caused by various noises has been carefully considered by a number of research workers during recent years. Before much work could be done along these lines, it was necessary to develop a method for measuring noise. The first measurements of noise were made by means of the audiometer, by which method the loudness of the noise being measured is compared with a sound of known intensity. The audiometer consists of a device capable of generating a sound or tone of a definite pitch or band of pitches, and the necessary control for changing the intensity of the sound. The test tone is heard through an ear receiver which is slotted so that the noise to be measured may be heard at the same time. The person who is to make the measurement first decreases the intensity of the test tone until it is so faint that it can just be heard,if made fainer it becomes inaudible. A sound of such intensity is at the threshold of audihility, the datum line for sound measurement. The test tone is then compared with the sound to be measured, and its intensity is increased until it is barely audible above the sound. Since the intensity of the test tone is known, it is thus possible to determine the intensity of the sound or noise just measured. The intensity is stated as being so many units above threshold, or if we use a scale where threshold is zero, we state the intensity as being a certain number of units. Or if desired, the hearing loss or deafening effect may be used to indicate the loudness of the noise.

The unit most commonly used at this time for denoting the intensity of a sound is the decibel. This unit was selected by the engineers of the Bell Telephone Laboratory to replace the transmission unit which was previously used to designate the same degree of intensity, and the bel, which is ten decibels. was derived from the name of Alexander Graham Bell. The decibel is a unit of sound intensity which is equal to ten times the common logarith of the intensity ratio. One decibel corresponds roughly to the slightest change in the intensity of a sound that can be distinguished by the human ear, and represents a small change in sound energy for low inten-

sities and a large change for very loud sounds. If a sound has an intensity of 50 decibels it has an intensity 100,000 times that of a sound that cauld be heard under conditions of absolute quiet, and it would cause a hearing loss of approximately 30%. By raising the intensity to 60 decibels, we have an intensity 1,000,000 times the minimum audible intensity, with a deafening effect of approximately 40%.

In making audiometric measurements the ear of the investigator becomes an indispensable adjunct to the apparatus and the human element is involved in the results. The efforts of a number of research organizations have been directed toward the development of a machine that would be capable of making noise measurements objectively and without bringing in the human element, and to date several devices have been produced. One of these, the Room and Street Noise Meter, being developed by the Bell Telephone Laboratories, is playing an important part in the noise measurement survey being made by the New York Noise Abatement Commission. The audiometer, which is being used by the Commission to determine the noise intensity for three distinct bands of frequencies, is being supplemented by measurements with the noise meter of the noise level. The noise meter consists of a microphone pick-up and apparatus for measuring the currents set up when noises cause the microphone diaphragm to vibrate. The microphone may be moved around in a radius determined by the length of lead or wire used, which permits the stationary mounting of the meter in a truck. Noises actuate the diaphragm thus setting up a flow of current in the circuit, which is amplified and measured, the reading being made from a dial. Noises of high intensity cause a greater vibration of the diaphragm than noises of low intensity, and the measurement of the variation in the electrical current is an indication of the noise intensity, made possible through proper calibration of the instrument. The dial reading gives directly the noise intensity in decibels above

Through the use of these two types of measuring devices a very comprehensive picture of the noises of a city is being obtained by the engineers of the Noise Abatement Commission. Measurements made at many stations about the city give not only the intensity of the noise level, but also indicate the range of frequencies or pitches which comprise the noise level at any point. After the measurements are obtained at many points throughout the city, it will be possible to draw a noise map showing the amount and type of noise present in the city. If at any time in the future it is desired

to know whether the city has become noisier through growth, or whether the noise level has been decreased generally or at certain points, the noise map may be used as a reference point for another survey. In addition the survey will be broadened to show the contribution of specific sources to the general noise level. For instance, the study will show the increase in the noise level at a street intersection caused by the passage of an elevated train, or the rumbling racket set up by a rattling ruck as it crosses the trolley tracks. Building operations are a source of many noises and the survey will show the part played by the riveter, the steam shovel, or the pneumatic drill.

Measurements were not necessary to tell us that there is noise present in the city; we have known that for some time—but they were necessary if we are to determine the amount, pitch, cause, frequency of occurrence, and the other data requisite to a careful and comprehensive study of the situation. A campaign of noise abatement must be based on reliable data if it is to be successful.

In discussing the definitions of noise, we made use of the term "annovance effect," in endeavoring to point out the necessity of considering more than amplitude, frequency, and quality, of a sound in the determination of what sounds are noise. What makes a noise annoying? Is it the loudness, the pitch, or some peculiar quality of the sound? In an effort to answer this question Dr. Donald A. Laird has performed some very interesting experiments in his psychological laboratory at Colgate University. He had trained observers listen to sounds of differing degrees of loudness and pitch in order that they might determine when each became annoying. In general his experiments indicated that sounds of equal loudness between 256 and 1024 in frequency-that is between middle C and two octaves above-were less annoying than sounds below or above this range of frequencies. It was shown that at 512 cycles-or an octave above middle C-an intensity of 89 decibels was necessary to make the sound as annoying as 8192 cycles at 44 decibels. In general we might say that a noise of low frequency and high intensity may be less annoying than a high frequency noise of low intensity. In this connection Dr. Laird, says, "It is of considerable theoretical interest that those pitches which man himself makes in speech are the least annoying to him. The annoyance of certain tenor and soprano voices where higher pitches occur is in line with our findings. The low annoyance values of the more common speech sounds may represent a biological adaptation."

It would appear that this is the proper time to ask another question,-are sounds which are annoying harmful to the human system? While the fact that a noise is annoying does not prove that it is in any way harmful to human beings, it does indicate that it is not helpful. We know that certain types of noise speed up the mental and physical processes of certain types of persons, but it does not follow that this is proof that the noise is not harmful, for its long continued effect may bring injury in its train. And because noise in certain quantities will decrease the efficency of a skilled worker, that in itself is not a proof of harm, since relaxation may entirely compensate for this loss of efficiency. We do know. however, that theoretical tests and practical experience show conclusively that there is a loss in efficiency as determined thru output, and a general condition of strain imposed on a body working in a noisy room; and that the reduction of the noise brings about a decided improvement in the general tone and efficiency of that body.

Some very interesting findings have been brought to light by workers who have been studying the effects of noise on human beings. It has been shown that the rate of burning of tissues, or basal metabolism, is increased 19% under conditions of noise; and that workers become fatigued after a shorter period in a noisy room than in a quiet room. Dr. Foster Kennedy, a member of the Noise Abatement Commission of New York City, has been conducting experiments on persons having a deficiency in the bony covering of the brain. By means of a partly vacuumized drum placed on the soft spot over the brain of an otherwise healthy person, and thru which impulses are transmitted to a needle travelling over a sensitized paper drum, it is found that the brain pressure is increased four times over normal by a sudden loud noise. And this increased brain pressure is apparent for an appreciable length of time after the occurrence of the noise; in fact approximately 30 seconds are required for a return to normal pressure. C. Landis has shown that the noise of a firecracker raised systolic blood pressure 20 mm. in 20 seconds; while I. H. Hyde and W. Sealapino report that the noise made by a telephone bell will accelerate the heart rate. Laird has found that accuracy in immediate memory for nonsense syllables was increased 15 percent and delayed memory increased 8 percent by reducing a complex noise from 50 decibels to 40 decibels. Witmack has proved that some auditory organs are completely destroyed by prolonged exposure to loud noise.

The findings of a number of other experiments on noise effects are at hand; and in

practically every case the indications are the same, that noise does have a marked effect on the body, and in many cases this effect is harmful. This should not be interpreted as implying that this particular field of research has been well covered, for the contrary is the case. The field has been little more than scratched, and at this time several laboratories have ambitious research programs under way, the results of which will be of great interest and of help in answering some of the questions that are now debatable.

A great many business organizations have been shown rather conclusively that noise is costly, if not actually harmful. For instance, a group of office workers engaged at a variety of machine operations showed a 12 percent increase in output when the noise level was decreased from 45 decibels to 35 decibels. Again referring to the tests of Dr. Donald A. Laird we find that the output of experienced typists was increased 4.3 percent when the noise level of their work room was reduced from 50 decibels to 40 decibels. The typists slowed up in the noisy work room during the two hour test periods, and had a tendency to warm up and gain speed in the same room 10 decibels quieter. A 42 percent reduction in errors in the telephone operating room of a telegraph company, and a 3 percent reduction in the cost per message, followed lowering the noise level from 50 decibels to 35 decibels. More and more business men are following Mr. Babson's advice to "remove noise from the payroll."

Mark Twain, who by the way agitated against noise in New York City, made a statement concerning the weather that can be paraphrased to sum up the noise question. A great many people have talked about noise and its harmful and annoying effects, but no one has done anything about it. Well, the Noise Abatement Commission of New York believes that a great deal can be done to improve existing conditions, and is now developing ways and means for bringing relief to the several millions of city dwellers whose ears are assailed by noise from sun-up to sun-down, and then on around the clock in many cases. It is not an easy task by any means, and certain noises, such as those from fog horns, are unavoidable; but by studying each source and then applying the right remedy, a marked improvement can be brought about.

At the present time there are laws prohibiting certain noises within the city, such as the unnecessary blowing of automobile horns, cut-outs on automobiles, and the use of exhaust whistles on trucks and motor cars. If these laws were suddenly enforced not only would the courts of the city be swamped with cases, but most of the police force would be off duty while waiting to appear in court. Obviously, then, the mechanics of enforcing these laws must be changed, or the drivers of cars must be educated to the point of realizing that the production of unnecessary noise is an act to be compared with expectorating on parlor floors. The same application may be made to the person who insists on having his radio play for every person in the block or building. And then there is the matter of the riveter, the pneumatic drill, the rattling and backfiring truck, the subway and elevated and surface cars, the shriek of the fire engine siren, and the clang of the emergency truck's bell, and many other sources of distracting noise that any city dweller can name off as rapidly as his A B C's. And to forestall accusations of bias we will add to the partial list, the banging of ash cans and the barking of dogs.

Certain of these noises will be greatly reduced or eliminated through improved or changed methods, materials, and equipment of construction and of transportation, which may be some little time in coming, but which are surely on the way. Others will be abated thru the passage of new ordinances or the modernization of old. In the final analysis, however, Mr. John Citizen will get help when he is willing to turn to and help himself. It is surprising what an aroused public opinion will accomplish once it is stirred up sufficiently.

There will always be noise in our cities, of course,-and who would want to live amidst the silence of the tomb? There may be too much noise to suit some people, and too little to meet the exacting requirements of others. Those noises that can not be abated at their sources, or at least, not for some time to come, may be prevented from sweeping through our buildings and disturbing us while at work, rest. or play, through the use of proper methods of construction. Windows may be of double construction; walls, floors, ceilings, and partitions may be erected in such a manner that the amount of noise penetrating will be negligible; and that noise which is generated within our offices, our restaurants, our hospitals, our homes, and which is a necessary accompaniment to our activities, may be largely absorbed and blotted out. There are ways, then, of circumventing and rendering impotent that comparatively modern enemy of man which we have dubbed noise.

# HAY FEVER: THE SUMMER TYPE. STUDIES IN HAY FEVER—III By A. A. THOMMEN, M.D., NEW YORK, N. Y.

In THE major portion of the United States there are recognized three distinct types of hay fever; the spring type caused by the pollen of trees; the summer type due chiefly to the pollen of grasses; and the late summer—early autumnal type caused by the pollen of weeds.

The spring or Tree Type, will be treated in a forthcoming paper. In the present article the summer, or Grass Type, will be discussed in

detail.

General Considerations: In three respects grasses constitute an extraordinary family of plants: (1) They possess numerous structural peculiarities which sharply define them from all other kinds of plants; (2) In most sections of the globe they contribute a large part of the general vegetation, frequently constituting the dominant feature of the landscape; and (3) The universality and supreme importance of their uses, especially in relation to the food of man and beast, gives them preeminence among all families of plants. The true grasses are of more value as sources of food for man and the domestic animals than all other forms of vegetation combined. Their importance is readily appreciated when we consider that all the cereal grains, wheat, corn, oats, rye, barley, rice and millet are grasses, and that these constitute the food staple of at least four-fifths of the human race. Until within recent years the entire sugar supply of the world was obtained from a grass, and fermented grains have supplied most of the alcohol needed in the arts, sciences and manufactures, and for slaking a goodly portion of the thirst of the bibulous. Certain kinds of paper and cordage are made from grasses, and the fungus Claviceps purpurea, from which is derived the valuable medicinal product ergot, is parasitic only on grasses, chiefly rve. The importance of the grass family reaches its greatest eminence in those regions of the globe where bamboos-members of the grass family, in just as good standing as our common timothy, red-top, wheat, etc.—through their exuberance of growth and ready adaptability to the most numerous and varied uses, actually represent the sine qua non of existence for millions of individuals.

What the cereal grasses are to man, the pasture grasses are to one of the largest and most important groups of mammals—the Ungulata or hoofed animals, comprising horses, oxen, cows, calves, sheep, goats, antelopes, deer, llama, etc.—the camel and the elephant, splendid servants of man in distant lands.

Number and Distribution: There are more than 3500 species of true grasses, comprised in 400

1 Thommen A A Hay Fever The Spring Type Studies in Hay Fever—II The Medical Journal and Record, May 21st, 1930

with an

genera. In terms of the number of species, the grass family occupies fifth place after the composites, legumes, orchids and madderworts. The grass family, however, is of first importance, owing to the countless myriads of individuals, far excelling any family; and their almost universal range-for grasses are to be found in all parts of the world, wherever there is sufficient soil to permit growth-from the equator to the arctic, from the scorching sandy sea borders of tropical lands to the highest alpine limits of perpetual snow. They are found in the swamp and the desert, the woodlands and the plains, and on the floor of the densest forest. It is estimated that this single family, with its 3,500 species (there are altogether about 220 families of seedbearing plants, with 133,000 species) actually constitutes one-sixth of the vegetation of the globe.

Size of Grasses: Grasses vary in height from less than an inch (especially Alpine and Arctic species) to several feet (corn) in herbaccous species. The bamboos, which are tree-like grasses, are frequently over 100 feet tall and more than a foot in diameter. There are certain clambering species which climb up through the trees for 40 feet or more. The vigor and abundance of growth of grass is quite astounding. This is exemplified by the amount of hay produced by the following: Timothy has given 40,837 lbs per acre (17,356 lbs. when dry); Orchard grass—27,905 lbs., in addition to an aftermath of 11,910 lbs.; and Perennial rye-grass gave 7,827 lbs (when dry, 3,390 lbs.) per acre. (G. F. Scott-Elliot.)

The capacity of the grass family to bestow on man and the domestic animals such beneficence is in decided contrast to the malevolence of certain of its members, as manifested in the production of hay fever and asthma periodically, in many thousands of inhabitants, chiefly of the temperate zones.

#### THE MORPHOLOGY OF GRASSES

For a proper understanding of the importance of the grasses in the hay fever problem, a knowledge of some of their important morphological characteristics is necessary.

Grasses, collectively, are referred to as the Gramineae or Poacae, meaning "the grass family." (Gramineae is from the Latin, Gramen, grass; Poaceae is from the Greek, Poa, grass.)

In the old herbals, the word grasse, gres or gyrs meant any small green plant. In our modern vernacular language the term grass is still commonly used in a vague sense to designate every kind of herbage of small size. The term is also applied, generally in combination, to many plants of widely different relationships which pos-

رواهم المنظمة المنظمة المنظمة المنظمة المنظمة المنظمة المنظمة المنظمة المنظمة المنظمة المنظمة المنظمة المنظمة

sess, or are supposed to possess, some resemblance in foliage to true grasses. Thus we have Cottongrass (Eriophorum sp.<sup>2</sup>). Sea-grass (Ruppia maritima)-(Zostera marina); (Salicornia europaca); (Statice Armeria): Scorpion-grass (Myosotis scorpoides): Blue-eyed grass (Sisyrinchium sp.): Rib-grass (Plantago lanceolata): Knot-grass (Polygonum sp.) and Grass of Parnassus (Parnassia sp.)—none of these plants is a grass.

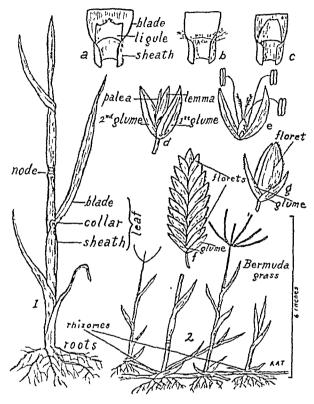

FIGURE 1

The structure of Grasses: 1. A typical stem. a., b. and c. Collar structure Timothy, Bermuda Grass and Red top, respectively. d. A typical flower. e. Structures within the lemma and palea. f. Spikelet of Stink grass (Eragrostis cilianensis); note numerous florets. g. Spikelet of Bermuda grass; note single floret. 2. Bermuda

Definition: Fig. 1. Grasses are mostly herbs with round or flattened (never 3-sided) hollow stems (called culms) closed or solid at the joints (called nodes) and 2-ranked (never 3-ranked) alternate parallel-veined leaves. The leaf has three more or less differentiated parts: (1) the sheath, which surrounds the culm, like a tube which is split down one side, the edges of which frequently overlap; (2) the blade, a free part branching from the sheath at (3) the collar, which serves to join the blade and sheath. On the inner side of the collar is the ligule, a small

membranous appendage. Occasionally the collar bears projections called auricles.

The above-mentioned characteristics are so distinctive of the grasses, that one can always readily decide whether a given plant is a grass or not, by looking for these characteristics. The only plants which may be confused with grasses are the sedges. In these, however, the culms are solid, are not jointed, and are nearly always 3-sided; the leaves are always 3-ranked, and the sheaths are entire; that is—not split down one side

The Flowers of Grasses: The spikelet is the unit of inflorescence, and consists of an axis (termed rachilla), bearing one or more florets in two ranks. A typical floret is composed of two bracts (termed lemma and palea respectively), which enclose the pistil, stamens (usually 3) and lodicles (usually 2), found at the base of the floret, outside of the stamens, in front of the lemma. At the base of the spikelet are two empty bracts termed glumes, which are referred to as the first and second glume respectively. A spikelet, therefore, is built on the simple plan of 2-ranked florets with a pair of glumes at the base. Both the grasses and the sedges (about 3,200), are characterized by the presence of glumes. These two families are referred to collectively as the Glumiflora.

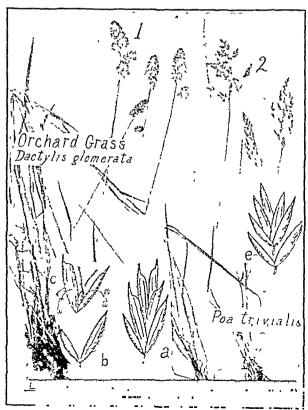

PLATE I

Detail of floral structures of (1) Orchard Grass; (2)

Meadow Grass. (See text.)

<sup>&</sup>lt;sup>3</sup> The abbreviation "sp." after a generic name signifies that no particular species of that genus is referred to.

These details can be readily mastered by referring to Plate I, Fig. 1, which depicts a specimen of ORCHARD GRASS (Dactylis glomerata). Fig. a, represents an entire spikelet, several of which are at 1. Note the two glumes at the base of the four florets. Fig. b represents the two glumes removed from the spikelet. At c. is shown a single floret, the lemma (at the left) and balea spread apart to show the three stamens and the pistal with the two feathery stigmas. lodicle is shown at the base of the pistil. When the floret is mature, the lodicles absorb moisture. the resulting turgescence causing the lemma and palea to spread apart. Fig. 2 is a specimen of MEADOW GRASS (Poa trivialis) with numerous delicate spikelets. A single spikelet is enlarged at e Note the glumes at the base of the three florets; the glumes are also shown removed from the spikelet.

The spikelet is therefore the unit of inflorescence of the grass family; and the unit of the spikelet is the floret. The 3,500 or more species of grasses differ one from the other, chiefly because of variations and modifications in these units. The variations in the vegetative system (root, stem, leaves, etc.) are slight, and of little importance in contrast to the modifications in the inflorescence (the reproductive system). A few of these important modifications are:

(1) The spikelets differ greatly in size.

(2) The florets may be one or many in number.

(3) The parts of the spikelet vary in relative size; the glumes may be large and the individual florets small; or vice versa.

(4) The glumes vary in size, shape, texture; they may be smooth or hairy; they may be reduced to rudiments, and are occasionally suppressed.

(5) The lemma may vary, as do the glumes. It may be minute, but is never absent.

(6) The palea is always 2-nerved, i e, it has two prominent nerves on its back. It also varies in size, shape, etc. It may be reduced in size and may, unlike the lemma, be occasionally absent.

(7) The spikelets may be unisexual (having either stamens or pistils) ie, not perfect. Sometimes spikelets contain perfect, staminate, and neuter florets (ie, those containing neither stamens nor pistils).

Any variations or modifications from the typical spikelet and floret are constant in a species, and within a genus.

TIMOTHY (Phleum pratense), an important hay fever grass, is of interest because of these modifications Plate II, Fig. 1, depicts an entire Timothy plant, with two spikes at 1, which contain several hundred spikelets crowded together, each comprising one floret. Fig. a. represents a single spikelet; note the glumes—and the contained floret, drawn separately at a\*.

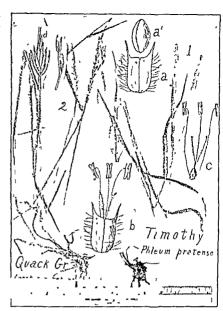

PLATE II

Grass (See text)

When the flowers are ripe, the organs (stigmas and stamens) contained within the lemma and palea of the floret protrude beyond the glumes as in Fig. b. Fig. c. represents the pistil and stamen after the glumes, the lemma and the palea have been removed. Note the lodicle at the base of the pistil Fig. 2. d shows a detail of a spikelet of QUACK GRASS (Agropyron repens). Front and side view.

It should be evident to the student of the hay fever problems that the grasses, by reason of their numerous, inconspicuous flowers, and their wide distribution, are evidently important causes of the malady. Clinical experience has proven the correctness of this surmise. As has already been emphasized, there are more than 3,500 species of grasses found throughout the world New York City, and within a hundred-mile radius, there have been recorded about 270 different species of grasses. Moreover, there is no time from early spring until the frost, when some species are not in bloom. Yet the grass-hayfever season in this section, is limited to a period extending from about June 1st to July 20th. Evidently, not all grasses are important factors in the hay fever problem

The question arises: Which grasses are impor-

tant causes of hay fever?

Five postulates have been formulated by the present writer, regarding pollen in relation to its hay fever causation.3 Unless a given pollen ade-. quately satisfies the requirements of all these postulates, it cannot be an important cause of hay fever. Their application to the grass-hay-fever problem will now be considered.

1st Postulate: The pollen must contain an excitant of hay fever. It is probable that all species of grass pollen possess the capacity to produce hay fever in specifically sensitive individu-The excitant or excitants are apparently present in different concentrations in different pollens. Most patients who are definitely sensitive to one grass pollen will be found sensitive to all other grass pollens with which they may be tested. It is not correct to generalize, however, for there are instances where patients, known to be markedly sensitive to several grass pollens, fail to react markedly to others. This seems to be particularly true of those individuals who have but recently developed hay fever. What appears. from our present knowledge, to be a safe generalization is, that a patient who is definitely sensitive to one grass pollen, most likely develops a sensitivity to all grass pollens to which he is adequately exposed.4

2nd Postulate: The pollen must be anemophilous, or wind-borne, as regards its mode of pollination. (For a more complete consideration of the question of pollination the reader is referred to the paper treating of the etiology of hay fever.<sup>8</sup>) Grasses, as a class, are wind-pollinated. Their small, numerous, inconspicuous, scentless and nectarless flowers have little, if any, attraction for insects. There is one phase of the problem, however, which has not been sufficiently stressed, particularly as regards the causation of hay fever by grass pollen, and that is the matter of self-pollination. There are many grasses which are neither wind-pollinated nor insect-pollinated—they are self-pollinated: that is, the florets do not open to have the pollen discharged into the air by the anthers. The importance of the matter of self-pollination is shown by

Chart I.

<sup>&</sup>lt;sup>3</sup> Thommen, A. A: The Etiology of Hay Fever; Studies in Hay Fever—1. New York State Jour. of Med., April 15, 1930, 437-442.

<sup>4</sup> In a forthcoming paper, the writer will discuss in detail with protocols, etc., of experiments, this phase of the problem.

Those which are italicized are important causes of hay fever, because they are normally crosspollinated (i.e., in this case, wind-pollinated). It is fortunate that wheat, oats, barley and rice are self-pollinated, because of the extensive areas of the globe given over to their cultivation. Crabgrass (Syntherisma sanguinalis), for example, rivals the ragweed as a weed in late July and August. It does not cause hay fever, however, because it is self-pollinated.

3rd Postulate: The pollen must be produced in sufficiently large quantities. As has been pointed out,3 flowers differ greatly in their capacity to produce pollen. Some grasses, though wind-pollinated, do not produce an abundance of pollen: such is the case, particularly with those species which, by habit, are highly colonial—i.e., grow in more or less circumscribed colonies.

4th Postulate: The pollen must be sufficiently buoyant to be carried considerable distances. The question of buoyancy has been discussed somewhat in detail.8 It is noted in Chart I, that Corn is normally cross-pollinated; moreover, the pollen is produced in large quantities, and is definitely active, yet it is not an important cause of hay fever, because it is not sufficiently buoyant, owing to its large size (80 to 110 microns). The question of buoyancy is intimately related to the size of the pollen grain. In Chart II the size of a number of grass pollens and plantain is recorded.

## CHART II

		Sise in
Botanic Name	Common Name	Microns
Argrostis palustris	Red Top	28
Agropyron repens	Couch Ĝrass	40
Andropogon virginicus	Beard grass	42
Capriola dactylon	Bermuda grass	26

Poa pratensis		
Secale cereale		
Spartina stricta		
Sorghastrum nutans		
Sorghum halapense		
Tripsacum dactyloides		
Zea mays	Corn	90

5th Postulate: The parent plant producing the pollen must be widely and abundantly distributed. The importance of this postulate may be exemplified by a consideration of rye (Secale cereale). In large areas in continental Europe, rye pollen is a cause of hay fever of outstanding importance, because it is so extensively cultivated, and is consequently a so-called escape over large Hence, its importance has been demonstrated. It is found in New York and vicinity, but so sparsely that it is not a factor.

The grasses found in the north-eastern section of the United States, which satisfy adequately the requirements of the five postulates are chiefly: Timothy, Red Top, Orchard Grass, June Grass, Sweet-vernal Grass. Their periods of pollination, together with several others of minor importance, are shown in Chart III. Most cases of grass pollen hay fever in the section under consideration have their onset about May 30th, and terminate about July 20th.

found as an escape from cultivation, that is, as a weed.

The pollen of Timothy is quite light, and will float many feet in a scarcely perceptible current of air. In a strong wind it is carried considerable distances. The blooming process begins at the upper portion of the spike and travels down-

CHART III

Pollination periods of several grasses growing in the northern portion of the United States. The grass hay fever season (end of May to end of July) is determined by the combined pollination periods of the several species. Note that Timothy does not begin to pollinate until mid-June.

The two most important hay fever causing grasses in the United States are Timothy and Bermuda Grass, because the excitant of hay fever is present in both pollens in large measure. It is chiefly an extract of Timothy pollen which is used in the northern states, and of Bermuda grass pollen in the southern and south-western states, in the treatment of grass pollen hay fever.

TIMOTHY (Phleum pratense) is the most important hay grass in America. There are 10 species of Timothy, only one of which is native to America, to wit, Mountain Timothy (Phleum alpinum), found from Labrador to Alaska and south to the White Mountains, and the ranges in the west. Common Timothy (P. pratense) was first brought into cultivation in the United States after it had been introduced from Europe long before the Revolutionary War. It was first cultivated by a New England farmer named Herd, and it was often called Herd grass. The first mention of the name Timothy is found in a letter written by Benjamin Franklin and dated July 16, 1747, in which he states that the Herd grass seed, recently received, proved to be "mere timothy." The name Timothy was derived from Timothy Hansen, who brought the grass from New England into Maryland, evidently prior to 1747. Its merits were soon recognized, and its culture spread throughout the country. In 1760, it was introduced into England as Timothy. The name has become adopted in all languages. Today, practically all grass grown for hay in the North-Eastern quarter of the United States and in eastern Canada is Timothy, either alone, or in mixtures. It is not surprising, therefore, that in this section Timothy is

ward, eight to twelve days being required for the entire process. The pollen is shed chiefly in early morning when the weather conditions are satisfactory. Timothy is an abundant producer of pollen; this may be deduced from the large number of spikelets densely crowded on the spikes which are usually 3 to 6 inches in length. (The writer has counted an average of 92 spikelets to the inch.) Timothy is a perennial, plants enduring as long as 6 years; and 15 years and longer in exceptional cases. The seeds are quite small, there being about 1,300,000 to the pound.

BERMUDA GRASS (Catriola dactylon) is the most important pasture grass in the Southern states, and is also an important hay grass in the same section. It occurs from Pennsylvania west to central Kansas and south to the Guli of Mexico; in Arizona, New Mexico and California. Bermuda grass is a native of India, where it is a much valued pasture grass, called doob or hariale. It was introduced into the United States about 1800.

Bernuda grass is a long-lived perennial with numerous branched leafy stems, commonly 4 to 6 inches high—under favorable conditions the stems may grow to 12 to 18 inches. It is one of the most aggressive of plants, few others being capable of growing with it. It produces numerous stout rootstocks (rhizones) about the thickness of a lead-pencil, which enable a single plant to cover an area of several square yards. If the soil is very hard, the rootstocks become runners (stolons) which spread above the ground for 1 to 4 feet. Because of these runners or rootstocks, it is almost impossible to eradicate Bermuda grass from an area after it has once gained a foothold,

for it has been demonstrated that a piece of rootstock one-quarter inch long is capable of developing into a new plant. The grass may be sown either as seed or cuttings of rootstocks and runners. Because of its ability to grow in any type of soil, and its creeping character, due to the development of rootstocks and runners, it is an excellent soil binder. It is used for this purpose on the levees of the Mississippi River, where it is very abundant.

Bermuda grass is one of the most important of lawn-grasses, owing to the fact that it forms a firm, even sod by means of its rootstocks and runners, and because of its marked ability to withstand close clipping. June grass, also known as Kentucky blue-grass (*Poa pratensis*) is the most important lawn grass in the North. It, too, is propagated by rootstocks and runners. In the South, more than 90% of the lawns are made of Bermuda grass. The spikelets are borne in clusters of 3 to 6 digitate spikes at the summit of the stems. The spikelets consist of one floret and are densely crowded on the spike. The seeds are very small, there being 1,800,000 to the pound.

PLANTAIN: Plantain is not a grass, though it is commonly called rib-grass. It is important to consider plantain in connection with the grass type of hay fever, because the pollination period of the hay fever causing species is in great measure coincident with that of the grasses. It pollinates from mid-May to mid-July, and then sporadically until about the middle of September. (See Chart.)

PLANTAIN (Plantago). Plate III. There are over 200 species of plantain of wide distribution. Twenty-four species are known to occur in North America. In New York and vicinity, eight species have been recorded, five of which are fairly common. The two most important species are the common plantain (P. major) and English Plantain (P. Lanceolata). Most species of plantain are chiefly insect-pollinated. English plantain is the exception in that it is mainly wind-pollinated. The common plantain was introduced into America from Europe in the early years of colonial development. It was known as "The White Man's Footprint" because it followed in the wake of civilization. The most important from the standpoint of hay fever causation is English plantain, a native of Europe, which is now a common weed everywhere in America, having been introduced as an impurity in grass and clover seed. It is a long-lived perennial, capable of growing in any soil that is well drained. Its leaves are long, hairy, ribbed and narrow at the base. From the midst of the leaves, which are basal, the stems arise which bear terminal spikes of flowers. These spikes are one to three inches long (much shorter than the common plantain). The flowers are minute, and though they are perfect, selfpollination is prevented by the pistil maturing

before the stamens, a phenomenon termed protogeny. (For a fuller discussion of this important phase of fertilization, the reader is referred to Note 3, page 580.)

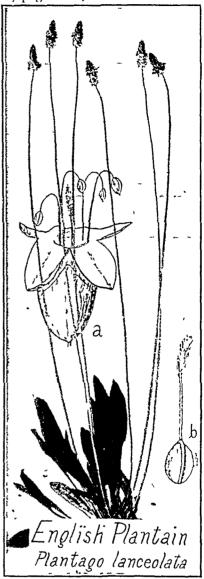

PLATE III

Detail of floral structures of Plantain. (See text.)

English plantain continues to grow throughout the greater part of the growing period of the year. If the plant be cut with a scythe after the spikes appear, other spikes will at once begin to grow in their place. It begins to flower in the latter part of May, and is capable of maturing seed during all the months following until the cold weather is near. The seeds are somewhat larger than the grass seeds mentioned, there being about 300,000 to the pound. English plan-

<sup>&</sup>lt;sup>5</sup> It is intended that only the major principles of diagnosis and treatment be mentioned in the present article. These phases of the hay fever problem will be discussed in detail in forthcoming papers

tain is a most troublesome weed in meadows and pastures It also infests lawns, roadsides, lanes

and waste places

Other common names used in various localities are ribwort, leechwort, ram's tongue, cat's cradles, chimney-sweeps, rattail, ripple grass, long plantain dog's ribs, headsman, jack-straws, hendlant, black-tack

Diagnosis The nature and character of the symptoms admit of little confusion in diagnosis. The symptomatic diagnosis is confirmed by the making of skin tests, mainly with Timothy pollen extract in the North, and Bermuda grass pollen in the South and West. If these be entirely negative, it is improbable that the case in question is one of hay fever of the grass type. Further investigation is necessary, however, and this should be made with other grass pollens. In addition to the grasses enumerated in Chart III, Bermuda grass (Capriola dactylon), Johnson grass (Sorghum halepense), Perennial rye (Lo-

hum perenne), and Canary grass (Phalaris canariensis) complete a list which most likely will cover any grass pollen sensitive case occurring in the United States, and most likely Europe as well

Treatment Experience has demonstrated that grass pollen sensitive cases occurring in New York and vicinity can be satisfactorily treated by the employment of a single extract, viz., Timothy It is doubtful whether the use of other grass pollen extracts, in addition, avail much The obvious principle involved is to treat the patient with that grass pollen extract to which the greatest reaction is obtained. In the writer's experience this has been invariably Timothy

It is well to make tests with plantain pollen extract as a routine measure in all cases of the spring type. If patients who give positive skin tests are proven to be clinically sensitive to plantain pollen, it will be necessary to give treatment with the latter extract, as there is no cross protection between the grasses and plantain

## PAROXYSMAL TACHYCARDIA IN A CASE OF DIABETES MELLITUS TREATED WITH INSULIN AND SYNTHALIN WITH COMPLETE RECOVERY

## By NICHOLAS LUKIN, M D, NEW YORK, N. Y

N November 4, 1928, I visited Mrs R S in response to an urgent call by her relatives, about 10 P M

She was in a grave state of anxiety and was attended by a nurse Those present in the apartment, husband, children and relatives were sad and dejected The woman was ill for four days and getting worse. A recent consultation between doctor and a specialist resulted in a grave prog-Upon reading the nurse's chart of the patient, the previous day's record stated "the pulse was very weak and very rapid, so that it could not be counted The patient was coughing frequently and perspiring Respiration labored Patient nauseated and vomited Complains of feeling dizzy Sleeping at intervals Respiration varied between 30 and 40 Temperature between 97 and 1005 Very cyanosed"

From my examination of the patient and questioning those nearest to her the following notes were made

Father died of Asthma when 65 years of age and mother of stomach trouble when 60

Patient, a mother of two healthy children She was ill with influenza in 1919. Eight years ago her weight was 200 pounds, upon dieting lost 50 pounds. At the age of 28 had one per cent sugar in her urine and was under treatment for a time, and then declared cured. Has had frequent spells of headaches with occasional dizziness lately. Menstruation is regular. Has had frequent attacks of palpitation for the past three weeks and on one occasion was brought home.

\*Presented before the North Bronx Mel November 14 1929

in a fainting spell Was then told of the presence of a high blood pressure which caused her dizziness, palpitation and fainting

Started suddenly with palpitation, severe vomiting and pain over the precordium in the sup-

ramammary region

A female of the brunette type about 36 years of age, well nourished, bearing an expression of anxiety and distress. Pulse proved almost imperceptible about 220. No murmurs were heard Pulmonary auscultation yielded broncho-vesicular breathing and numerous small dry rales at the bases. Rate of respiration was 38. The urine analysis resulted in the discovery of 6.5 per cent of sugar and the blood which was examined the next day proved to contain 0.330 mgms per 100 cc. There was no Ketonuria.

The sick room was darkened and all disturbing factors interfering with absolute rest eliminated as much as possible Head of the bed was placed in a modified Fowler's position and Colonic Irrigation ordered The ice bag to the precordium as well as the Digifoline which was used previously was continued Morphine sulpliate 1/4 of a grain without Atropine was given The next per hypodermic night and morning day, November 5th, the nurse's bedside notes were as follows 'Pulse appears slightly stronger Vomited seven though it cannot be counted ounces of dark colored fluid in the morning and ten ounces at 7 30 P M Temperature 100 per rectum" On this day after the blood sugar determination was reported at about 8 P M, 40 units of Insulin was administered and the usual inti Diabetic dict ordered November 6th The F nurse reported that patient was comfortable. Temperature 98.8. The pluse was rapid as on previous days but apparently stronger. Considerable nausea was present and vomiting occurred several times. Vomitus was of a lighter color and sometimes greenish. Stools were semisolid and considerable flatus expelled after two drachms of Comp. Licorice Powder. Patient expectorated a small clot of blood. Urine showed a heavy reduction.

Insulin 40 units was again injected and three tablets Synthalin in 10 mgms. doses ordered for the afternoon, one every four hours. Previous

orders were continued.

November 7th. Condition much improved. Pulse rate 80 and of good quality. No murmurs present. Apex beat defined in the fifth interspace and about 2 centimeters outside the midclavicular line. Cyanosis of face and lips has largely disappeared. Complains of gas and precordial pain, though to a lesser degree. The usual methods for relief were continued. Bedside examination of urine with Fehling's showed no reduction and the blood examination proved the presence of sugar to the extent of .220 mgms. per sugar 100 c.c. Insulin was discontinued and only Synthalin 10 mgms. with Camphor Monobromide 5 grains tid, to overcome nausea administered. Opiates were stopped and Luminal in 1/4 gr. doses given every three hours instead. digitales medication was stopped on my second visit because it seemed to leave no impression on the pulse.

Respiration was 20 and temperature 99 per rectum. Blood pressure was 110 Systolic and 80 Diastolic. From this day on convalescence continued in an uneventful manner. Her urine remained negative to sugar. The blood showed a gradual lowering of the substance being on successive examinations 0.190, 0.170, 0.160 and 0.158. The latter figure was reported on December 21st. Synthalin was continued. The diet was made more liberal and varied. The restrictions against carbohydrates were lessened.

On November 27th, about 4 weeks after the onset of her illness, the patient presented herself at my laboratory for a cardioligic examination. The findings were practically negative. Several electrocardiographic examinations were made. On November 27th, about four weeks after the onset of the tachycardia, revealed the only abnormality in the T wave, which was inverted in the 2nd and 3rd leads and attributed to the long and liberal administration of Digitalis. Another tracing was taken on December 11th. This exhibited the same abnormality to a lesser extent. The T wave in the 2nd lead becoming almost isoelectric, while in the 3rd it was less inverted than in the previous tracing. The gradual elimination of the Digitalis effect has changed the appearance of this wave. In a third electrocardiogram of

January 11th, a marked improvement was noted in the T waves of the 2nd lead, which was definitely upright and above the base line. The amplitude, however, is small. The third lead did not change greatly. A fourth tracing, taken on February 6th, 1929, almost three months after the onset of her illness showed no definite further improvement in the T waves.

Paroxysmal Tachycardia as defined by Thomas Lewis is a regular tachycardic which begins and ends quite abruptly and which is presumably ex-

tra-systolic in origin. \*1.

The auricular musculature which normally exerts the functions of contractility and tonicity for the propulsion of its blood content to the ventricles, thus obeying the normal impluses of the "Pacemaker" suddenly assumes the additional function of giving off impulses of its own accord and establishes a new ectopic focus. auricular node thus becomes submerged and the new impulses issue with great rapidity from 150 to over 200, the ventricules imperfectly contracting with each stimulus. When these impulses are not much above 200 the ventricles respond regularly though with a greatly lessened force. The diastoles are shortened, the left intraventricular pressure is diminished, due to imperfect filling and the right heart becomes engorged. If the condition lasts for any length of time the usual consequences of right ventricular stasis appear. Fortunately, the attack is of short duration and the symptoms vary accordingly. Thus, we may have pallor and fainting due to cerebral anaemia. \*2.

"A single paroxysm may consist of six or more beats; it may continue for an hour, a day, a week or more without interruption. Paroxysms lasting for more than ten days are extremely rare."

Synthalin was used on this patient as an aid to Insulin. Its use was suggested by a careful study of the drug by A. J. Ringer, S. Billon, M. M. Harris and A. Landy, which appeared in the Archives of Internal Medicine, April 1928, Vol. 41, pages 453-471.

In order to avoid overdosing with Insulin it was thought safer to administer a slower acting anti-diabetic drug and keep this up when the urine became negative to Fehling's solution and the blood still showed a relative high sugar content.

This case is presented in order to illustrate Diabetes as one of the possible causes of Paroxsysmal Tachycardia and its ready control by ap-

propriate medication.

The electrocardiograms prove the absence of evidence of intrisic cardiac pathology, except for the inverted T waves, which probably was caused by the Digitalis medication, as they gradually became positive and normal in subsequent tracings.

# THE DOCTOR LOOKS AT JOURNALISM\* By LINSLY R. WILLIAMS, M.D., NEW YORK, N. Y.

This glance at journalism, or as it might more properly be called, the daily newspaper, raises a question as to the function of a newspaper. If one had asked William Cullen Bryant what was the function of a newspaper, he might have replied, "A newspaper is published for the purpose of improving the taste of its readers in litera-Horace Greeley might have said, "The newspaper is published in order to tell Mr. Lincoin how to win the war or to persuade young men to go West," While Charles A. Dana would undoubtedly have thought of the newspaper's function as one which would induce young men in poor health to go to sea. All of them, however, would have agreed that the primary function of the newspaper was to mould public opinion.

It is quite evident that at the present time the primary function of the newspaper is to make money for its stockholders. It is recognized that a newspaper cannot make money unless it publishes a true account of the news (by the publication of human interest stories) promptly, and has a sound editorial policy and a circulation large enough to obtain a sufficient amount of advertising.

The press knows far better than the medical profession what is news and they recognize that it is the unusual, the unnatural and the horrible which appeals to the reading public while the humdrum affairs of our daily existence are not news.

There was a story in one of the newspapers recently of a little girl of six who had her leg caught between an elevator and the floor. It was impossible for her parents to extract the foot and an ambulance was sent for. The doctor climbed on a ladder from below the elevator, took off the child's shoe and stocking, greased her leg and managed to extract the child from her predicament without even a scratch. Here is a bit of news with human interest in it which is unusual. If this same child had fallen on the sidewalk and broken her leg, it would not have been news unless her father or mother held an important position in the financial or social world.

The modern press has a definite editorial policy, frequently political, but some specialize in different fields, giving emphasis to education, international affairs or other incidents in human life varying with the personality, character and experience of its editorial staff.

The modern press has taken a more active interest in the progress of science and medical affairs during the past two decades. The

\* Read before the Medical Society of the County of New York, Tebruary 24, 1930.

reader may now find a considerable amount of educational material of a medical nature in the daily press. The medical policy of a newspaper will naturally vary as does its policy in other fields. Many of us remember the way in which the former editor of *Life* was want to attack the medical profession and everything about the art and science of medicine. We know also that there are dailies in New York City which still belittle the medical profession and its effects.

On the other hand, there are newspapers which endeavor to furnish their readers with all the news available of a medical nature and strive to educate their subscribers in a manner of which any physician would approve.

Physicians, however, must remember that newspapers do not exercise a censorship of news, and that they will report as news discoveries of cures which are not curative. Until the last few years the papers have had no accurate source of information on medical affairs.

There is no doubt that the press will co-operate gradually with the medical profession in moulding public opinion on medical questions, but no order to do this the press must be furnished by the profession with news items advising them in advance if there is any human interest in a medical incident and also providing material for special feature stories. Many of these feature stories express the opinions of the writers but do not express the opinion of the editor.

Recently there was published in one of the evening papers a story on the value of painting the arteries with a preparation of carbolic acid, stating that old age may be deferred by this method. This story came from Europe written by a special writer on the paper and it was unusual. Consequently it was news. On the other hand, from the medical point of view, the article was valueless because one could not tell what arteries were painted, the exact nature of the solution used, or what the underlying theory of the procedure was.

Similarly another newspaper published a story prepared by a special news writer stating in effect that physicians were loathe to accept the statements of others and that Pasteur's teachings were not accepted at first, and that doctors opposed every new advance in medicine. The newspaper in question, however, promptly published a letter from a physician correcting the statement, proving that the editor's views were not the same as that of the news writer.

It is a matter of great satisfaction to many of the medical profession to note that the modern newspaper is willing to refuse advertisements for therapeutic measures when they are either untrue or misleading. It is recognized that advertising

 $\mathcal{A}_{2}$ 

is the main source of the newspaper's interest and when a newspaper goes to the trouble of questioning many advertisements and refusing or demanding that the wording be changed in many others, it is definite proof that the press has some knowledge of ethics as well as the medical profession.

Physicians are interested in medical publicity and have frequently criticized the press, but no more vigorously than the press has criticized the medical profession for its attitude of secrecy and mystery. The press must understand that as a prospective patient does not know what he proposes to purchase from a physician or the value of the purchase after he has received it, the best advertiser may become the busiest of physicians. Some of the people may be fooled all the time, and as our population is so large there are a sufficient number to be fooled daily to keep the advertising physician very busy. The practicing physician, therefore, desires to keep his name out of the newspapers primarily for the protection of the public.

There is a difference, however, in the announcements to the press being given by medical organizations, particularly county medical societies, academies of medicine and national organizations, which are educational in value, and many of our societies, in particular the American Medical Association and the national organizations, render a conspicuous service by furnishing the press with abstracts of papers read at their meetings which denote the progress of medical science and instruct the people.

In New York an endeavor has been made to furnish the press with the type of service which has just been indicated by means of the Press Relations Bureau which is maintained under a joint committee of the Medical Society of the County of New York and the New York Academy of Medicine.

## POPULAR EDUCATION

There are many physicians who believe very earnestly that the health of the people would be better if they lived more hygienic lives and took more precautions which would prevent communicable diseases; and that if the people were more regularly examined by physicians, many difficulties would be detected early and proper treatment could be instituted which would postpone the effects of disease. It is believed that tuberculosis and diphtheria can be largely prevented if the people are sufficiently informed and that death from cancer may be postponed if operations are sufficiently early.

For many of these conditions active propaganda is being carried on by voluntary societies, each of which have been organized and maintained by physicians, and in order to further the

popular education on the subject physicians in private practice (as well as others who may be officers or members of the boards of these associations) give lectures or talks over the radio. In order to further the effect of the physician's lecture, a summary of it is often provided in the daily press. There are some physicians who believe that this practice is a species of advertising on the part of the physician and perhaps it does bring him an occasional patient, but he is entitled to an additional patient if he is willing to give the time to the preparation and delivery of an address whether to a visible or invisible audience and it does not add to his professional standing. Experience over nearly thirty years testifies to the difficulty of securing physicians to carry on this type of work, the rewards for which are very slight. It is impossible to avoid the use of the speaker's name, for it is hard enough to get an audience even with the use of the speaker's name and no newspaper will print a summary of an address without the name of the speaker.

It is evident, however, that there is a group of physicians who are quite ready to speak over the radio or to write a magazine article on some phase of medical activity, acting under their own initiative and not under the auspices of an organization. The organizations, as a rule, are careful in the selection of their speakers and the addresses are usually of a type that does not draw The free lance, however, frequently manages to get his address in somewhere and if his subject be the prevention of disease, he is careful to explain how he treats people in his private office. This last group of individuals have occasioned a great deal of annoyance to the profession and brought about the formation of a committee for the control of radio talks and the New York Academy of Medicine requires its Fellows to submit magazine articles and radio addresses to the Medical Information Bureau.

## INSTITUTIONAL PUBLICITY

I refer here particularly to hospitals of all kinds and dispensaries which frequently have news to get out and also have a definite desire for publicity. The news is rare but publicity is rather frequent and is usually carried on when a campaign is being waged to secure funds for a new building or additional endowment.

Many physicians think that the hospitals and dispensaries are taking an unfair advantage of them when these institutions carry on a publicity campaign because the institution gives out the names of the prominent men on its staff.

On the other hand, we must realize that if the institution makes an appeal to the public, it must obtain the public's confidence and among a small number of large givers the individuals recognize

the names of physicians of prominence and their confidence is gained by this method. I do not see how this can be avoided. Unfortunately, when such a campaign is being carried on the publicity agent is seized with an advertising mania and is prone to exaggerate the advantages of the particular institution and to make it appear to the public that this institution is better than any others and that its medical staff will give better treatment than can be obtained from any private physician. This is obviously unfair, and there is but one way to control it and that is by asking the staffs of the various institutions to submit propaganda material to the Medical Information Bureau before releasing it to the press.

#### MEDICAL ORGANIZATIONS

Organized medicine frequently has a message to deliver and at many of the meetings of the five county societies papers are read which are of public interest and many more which are not. The average reporter not trained in medicine might think that the report of several cases of Colles' fracture at a Section meeting was a description of a new disease. On the other hand, he might fail to see that a new test for renal function might be of great value.

The county society should have a committee. one of whose functions should be to review the programs and titles of papers and have them submitted in advance and select from them those which have news or educational value. should be released in advance and the representatives of the press should be invited to the meeting and permitted to interview the speakers. I know there are many who will hold up their hands in horror at the idea of the speaker's name being mentioned, but I cannot see that a statement has any news value which says that Dr. X, who declined to give his name, spoke at the county medical society last night and described a marvellous improvement on the method of removing the spleen. This is not news. It is simply publicity for the county medical society and will not be published by the press.

Matters of medical policy which are discussed at the meetings of the county society, resolutions which are adopted, reports of committees which have a bearing on civic policies of all kinds, sometimes have news value and if consistent with the society's policy should be furnished to the press and the chairmen of these committees should sense when they have a story which is of

real interest to the public, and the reporters should be given an opportunity to obtain that story in advance.

What would be the effect of such a policy upon the individuals whose names were used frequently in the press? Would it increase their practice? They might get a few additional patients, but their names would only be used by and with the consent of a committee of the Society and they would not be reading papers very frequently.

There is a great educational value in the press releases issued during the progress of our national medical society meetings, state society meetings and others which do one definite thing. They stimulate the interest of the public in medical affairs, increasing the confidence of the people in the medical profession and collectively stimulate business.

#### COLLECTIVE ADVERTISING

Last October and November the five county societies in New York City launched a campaign of propaganda and advertising in favor of health examinations. Although this was primarily in the interests of the public, no one can deny that it was also in the interest of the medical profession. There is no doubt but that the majority of the members of the profession did not notice from their office attendance that the campaign was going on, and these individuals may have felt that the campaign was a waste of time and money-but we must remember that producers and distributors of dairy products, fruit growers associations, soap manufacturers and others advertise collectively the use of these commodities without necessarily mentioning the name of the individual concern.

I believe that it would be of great value to the public if the county society advertised more and more, and it would ultimately redound to its credit, and that it would not hurt its business. We live in a commercial age, an age of publicity, in an enormous city where no individual can keep pace with the daily doings, comings and goings of the populace, and we must modify our views to meet the views of the times. Although physicians may still be gullible in Wall Street matters, their business acumen has enormously increased during the last two decades and business is only the first cousin of commerce. Business and commerce cannot thrive if they keep hidden under a hushel.

# TRAUMATIC NEUROSES OF THE EYE, EAR, NOSE AND THROAT\* THEODORE H. WEISENBURG, M.D., PHILADELPHIA, PA.

HE traumatic neuroses of the eye, ear, nose and throat differ in no way from the neuroses of other parts of the body. Rarely are the symptoms limited to the eye, ear, nose or mouth, and usually we have accompanying such phenomena general symptoms which are common in all neuroses. It is well therefore to discuss the problem first from the general viewpoint.

To begin with the neuroses which follow trauma are in no way different in their general character from non-traumatic neuroses. They are exactly similar in their symptoms to the type of cases found in the war, so-called shell shock cases. Perhaps a better way of designating them would be post-traumatic neuroses, for they follow trauma.

Anyone who has a large experience with neuroses, and mine extends over 25 years, is impressed with the development of these cases. If I were asked what my outstanding impression was of the cause of the development and persistence of the symptoms I would say without hesitation, bad handling on the part of the physicians who first come in contact with the injured, and the subsequent treatment in the first few weeks following the trauma.

Usually after an injury, particularly in the nonsurgical cases or sometimes in surgical cases, the patient, who is more or less fearful of the consequences of the injury, is either casually examined by the physician so that he is dissatisfied with what has been done for him, or what is more common, a suggestion is thrown out on the part of the physician of a greater injury than he actually has and immediately a fear is put into the patient's mind that he may have an irreparable injury which will incapacitate him for life. All these impressions could of course be removed if the patient's viewpoint is understood, if he is thoroughly examined, told what is the matter with him and what the effect will be and what treatment is indicated, and following this is intelligently handled. But in the cases which are called to my attention a slip-up is generally made somewhere in the line and the consequence is that insufficient attention or poor applications of common principles of psychology bring about a neurosis which may continue for the rest of the patient's life.

If one follows the development of the neuroses it is at once obvious that such symptoms do not follow the trauma immediately but are of gradual development, there being usually one little incivient which finally fixes the symptoms in the parameter from a week to two or three months.

Week to the Medical Society of the Medical Society of the Week, at Utica, N. Y., June 5, 1929.

A certain number of the neuroses are the resultant of poor mechanical treatment. This is particularly true following injuries to the skull and concussions of the brain as a result of which so many symptoms referable to the eye, ear, nose and throat are developed. It is obvious that in any patient who has had a concussion, which means a shaking up of the cranial contents, there must be a certain amount of actual organic change. The longer the period of unconsciousness the greater the trauma. In most instances following such an experience where a neurosis has developed, the patient has not been kept in bed long enough. I have seen the same error made by neurosurgeons following operations for brain tumor. too much of a hurry to get rid of patients. In my judgment nothing needs more time than a readjustment of the cerebral situation following trauma. Moreover, especially in persons over fifty, it is well to consider that some symptoms may not develop until the convalescence and during the period of readjustment.

My own feeling is that in all cases of cerebral trauma there should not only be a thorough neurological and x-ray study, but also a complete investigation of the spinal fluid with pressure readings, a complete eye examination including field studies, complete ear study including vestibular tests, and the usual nose and throat examinations.

While this investigation is made it should be remembered that the patient has a viewpoint based upon a fear that something is seriously wrong with him, and it would be well if no remarks were dropped by the examiner as to possibilities of diagnosis, for no one is more eager to pick up such possibilities and give the worst interpretation to them than the patient.

In my experience only a small percentage of claimants are mallingerers. In Pennsylvania, for example, where the average compensation is never more than \$15.00 a week, it hardly pays an individual, especially one with family responsibilities, to continue his symptomatology. On the other hand, care must be taken to judge each patient by his merits. This is particularly true of individuals over fifty who may not be able to get their jobs back. On the other hand, one can readily understand how a woman over fifty who has been earning only seventeen or eighteen dollars a week, would prefer to get an extended holiday on fifteen dollars a week.

Frank hysteria is common. Cases of blindness or loss of hearing, or inability to swallow or talk, are however unusual. They of course occur in a certain number of cases but are not the rule. They are easily curable providing of course one recognizes that it is a case of hysteria and knows how to cure such patients.

## Influence of Focal Infections and Other Extraneous Causes

It is well recognized that just as in any other psycho neurosis, focal infections such as bad teeth, tonsils and gastro intestinal conditions may be the cause of the continuance of the symptomatology and frequently symptoms will not disappear until

such infections are removed In this regard syphilis plays a very important It is now well established that trauma may be the precipitating cause in the relighting of an old syphilitic infection, that is, if an individual had not been injured the active manifestations of neurosyphilis may not have become apparent for some time This subject is of great interest and is very important in compensation work should not be always assumed that merely because a person has syphilis all the symptoms are therefore referable to this disease. On the other hand, it cannot always be taken for granted that in every case of trauma of the nervous system the syphilitic symptomatology is precipitated Each instance will have to stand on its own merits but it is well to keep this relationship in mind

## Relationship of Cerebral Trauma

It can be taken for granted that trauma in parts other than the head rarely gives disturbances in the eye, ear, nose and throat, with the exception of dizziness, which is a common symptom of a general neurosis. It is an axiom in the traumatic neuroses that the local symptoms follow an injury in the part, and this is equally true of the head For example, if an individual is injured in his ear the consequent symptoms will be referable to this organ. The degree of the symptoms bears no relation to the amount of the trauma, for as is well known, frequently slight trauma may give the largest train of symptoms.

Following concussions of the brain or injuries to the head the commonest symptom is dizziness. While a certain proportion are undoubtedly due to an involvement of the labyrinth, the largest number are purely psychoneurotic in origin.

An analysis of most of the descriptions of dizziness shows that most of them are based on the fear of falling or staggering. Some of the descriptions are rather bizarre, for example, a curling feeling over the head and eyes, a crawling feeling in the head, with dizziness objects got larger and larger and then broke up and were seen in all colors, a dragging and cringeing feeling back of the head through the ear, a flickering before the eyes, pain in the ear, a flickering before the eyes, one patient stating that when he looked to the right objects would go to the left, when to the left objects would go to the right These descriptions of dizziness could be carried on indefinitely

In many there has been an actual labyrinthine involvement in the beginning, the symptoms either

disappearing or lessening in the course of time, but fear on the part of the patient had caused a persistence of dizziness. Where there has been no concussion the dizziness may be vasomotor in character. It is not at all uncommon in neurotics to have numbness or coldness, flushings or a feeling of heat. I believe that the same cause may produce dizziness.

While dizziness and buzzing in the ears are the common symptoms, fear of loss of hearing is frequently present following trauma of the ear

## Vestibular Symptoms

While the examination of the vestibular apparatus by so called Barany method is of the ut most importance, care must be exercised in not placing too much reliance upon unsupported find-Up to date there is very little data as to the vestibular findings in functional cases. I have been in the habit of referring all of my dizzy cases for a vestibular examination and not infrequently the findings by competent men have indicated lesions in the posterior cranial fossa In a number of instances the subsequent history of such cases has shown that with the settlement of litigation, all of the symptoms, including dizziness, have disap-This is not a reflection upon the examiner, for if neurologists frequently err in the differential diagnosis between organic and functional diseases, similar difficulties may occur in the realm of the vestibular apparatus and its related tracts I have had many instances of choked disc diagnosed by competent eye men only to find later on that they were examples of pseudo neuritis

My own attitude is that no tests whether they are vestibular, ocular, sinus or otherwise should be accepted unless they fit into the general symptomatology. As a rule clean cut opinions, particularly in the present status of our knowledge of the vestibular examinations, are rather foolhardy.

## Eye Symptoms

Most eye symptoms consist either of a fear of loss of sight or of irritating visual phenomena such as spots before the eves or temporary blindness or dizziness when trying to read Sometimes twitching of the eyelids is interpreted as a failure Usually there is no difficulty in differof vision entiating functional visual loss. While I am on the subject it might be well to insist upon the importance of field examinations From the neuro logical standpoint a routine eye examination gives more information than any other but usually field reports are lacking This is probably because of the time consumed in such an examination have long been in the habit of sending all such patients to the younger man who has plenty of time, rather than to the older and busier ophthal mologist

One frequent complication which must not be neglected is that traima, especially around the neck, might be the exciting cause of a gotter caus

ing exophthalmos with the attending train of

symptoms.

Injuries to the face, especially to the jaw and mouth, are not uncommon and are frequently accompanied by the usual symptoms which consist of disturbance of speech or of inability to open the jaw or swallow. Not long ago a patient who had a trauma in the upper lip claimed that he had developed disturbance of speech which rendered it impossible for him to be understood so that he had to give up his job. Examination showed that his speech was like that of a paretic with tremors in his face and tongue. His pupils were irregular and the reflexes were lost and subsequent serological study showed that he was a paretic. case illustrates very well the importance of always keeping in mind that in every instance when an examination is made a general examination is indicated.

Another man who was struck on the back of the head and neck claimed that he could not talk because of a pain in his neck and a crawling feeling in his head. The symptoms eventually disappeared.

Another man of 32 was struck on the left side of the jaw with a tool. The skin was not broken but his face became swollen and the left eye closed. He was not unconscious. He first went to the Company doctor who admitted him to a hospital and kept him there for six weeks, but nothing was done for him. He then left the hospital and went to his own physician who admitted him to another hospital where he was operated upon for a supposed dislocation of the jaw complicated by abscess. He then found that he could not open his mouth. The insurance carrier then referred him to a very good plastic surgeon who tried to heal up the site of the old operation. The surgical condition improved but the patient complained of the fact that the jaw clicked when he opened his mouth and he also had pain. Finally, after going through more medical handling, he came under my observation and was admitted to the hospital. He was very antagonistic and uncooperative.

Examination showed that in the first operation the upper part of the facial nerve was cut so that the patient could not close the eye. The jaw was in good position and could be opened. His chief resentment against treatment was that he was told that he was a mallingerer. As a matter of fact it turned out that he had consulted a great many physicians and had paid them out of his own pocket. There was no doubt in my mind that he had made a sincere effort to get well. He had been earning \$25.00 a week and was receiving only \$15.00 a week compensation, and was unable to support his wife and three children on this.

Another man of 41 was struck in the left face by an emery wheel, stitches were put in and he returned to work in about ten days. Following this he began to complain of a numb, dead feeling in the upper lip and inability to open the jaw. Examination was entirely negative. Inability to open the mouth and jaw was entirely of a hysterical character.

Another patient complained of difficulty in swallowing when he was drinking cold water, warm water did not bother him.

There are many instances in which there may be a combination of symptoms of the eye, ear, nose and throat. About the worst case with which I have come in contact was that of a man of fifty, with a negative history, who while stooping over was struck on the head by a board which threw him forwards. He was not unconscious but he felt stupid and his nose bled. There was some laceration of the skin at the point of contact. For about twenty-four hours he was well, then he got worse complaining of a pressure feeling with a sense of warmth to the back of the head and neck. He returned to work but stopped within a week because he was staggering all over, bumping into machinery, and since that time for a period of two years, during which period he has been under observation, he has not returned to work.

His history was rather interesting. He was referred to a hospital where x-rays were made of his head, but was told that there was nothing wrong with him. Following this he developed a whole train of new symptoms such as pain in the head, tenderness in the occiput and flightiness. He then began to stutter and it was thought by some that he had an organic nervous disease. With his eyes open he would stagger like a drunken man, but with his eyes shut this was much exaggerated, and at all times he would avoid objects in front of him and complained that he could not see well. After a period of hospitalization lasting over two months, practically all his symptoms disappeared with the exception of some dizziness and buzzing in one ear. However, no complete cure was ever accomplished because when he came into our hands the neurosis had been in progress about two years. He came to my clinic a week ago and while better, he still complains of symptoms and he is still on compensation.

There are other types of cases which have a resemblance in that patients complain that objects are retained in their eye, ear, nose or throat, such as the case of a man who said that he had a cement particle in his ear. He consulted his physician the day following the accident who removed some sand from his ear, but the patient complained of dizziness. Following this, on his own account he consulted a great many physicians and finally found one who removed a piece of cement from his ear forty days after the original episode. While he felt better for a number of hours afterwards, when I examined him a week later, he told me that he felt that he still had some cement in his ear because he had the same feeling in it. Besides he complained of impairment of hearing, roaring in his ear, pain in his neck and in his tongue, so that he occasionally could not use his

tongue for eating and talking. He also complained of some pain in his right eye and diminution of vision.

Examination by a competent ear man showed that his ear was normal. My own examination

showed that he was a psychoneurotic.

This is an interesting example of how a psychoneurosis was developed through fear and through bad handling by those who first came in contact with him.

Fears that objects swallowed still remain in the throat are not uncommon, or that there may be dust particles in the sinuses or the nose. Such patients are very troublesome unless adequately handled.

#### Pain in the Face

Pain in the face following trauma of the head is a common symptom. The diagnosis of pains in the distribution of the fifth and ninth nerves is now pretty well established, but the atypical pains are difficult of exact diagnosis. Whether they are functional, vasomotor, sympathetic or nasopalatine in origin cannot at this writing be definitely stated, but as a rule functional pains can be diagnosed because they are atypical in their distribution.

## Influence of the Law

There is no doubt that the mere fact that an individual may reopen his case any time he chooses causes a continuation of symptomatology in a certain number of patients. Lump sum settlement with no reopening is the best procedure. This has been tried in a number of States, particularly in California, with excellent results.

There is one aspect however which is very pleasant from the physician's standpoint, and that

is that as a rule hearings before the Referee are freely conducted so that the physician may give his full opinion without the usual wrangling and limitations of procedure which accompany similar cases before Common Pleas and other Courts. In this respect at least the physician has much for which to be thankful.

#### Treatment

From what has been said, the best method of treatment consists in the prevention of the neurosis. If examining physicians, particularly those who first come in contact with these cases would keep in mind the fact that every injured individual has a fear of the consequences of the injury, probably nine-tenths of the traumatic neuroses would be prevented. After the symptoms are once established a cure may be difficult particularly if the case comes to litigation.

From the standpoint of the insurance carrier it is a question of dollars and cents. The cost of the loss of an eye or ear will be balanced against the estimated cost of curing such an individual. Most enlightened companies, however, adopt the latter policy of attempting to cure the injured patient and they now have well conducted clinics with competent physicians who make every attempt to cure patients. In intractable cases the patients are admitted to suitable hospitals where every effort is made to cure them. Such companies find that this procedure is the least expensive for if the patients are adequately handled they are easily curable. Besides that the corporations have the consciousness of knowing that they are doing good work and in this respect physicians should do everything they can to encourage

#### AGE INCIDENCE IN PERFORATED PEPTIC ULCER

Statistics and Report of a Case Perforating at 18 years

By JOSEPH C. READ, M.D., BROOKLYN, N. Y.

From First Surgical Service of the Methodist Hospital, Brooklyn, N. Y.

D. Number 133625. A single, white, American male entered the Methodist Hospital, via ambulance, on September 25, 1929. One hour before admission, while operating a pneumatic drill, he was suddenly scized by an excruciating pain in the upper abdomen. This was non-radiating and caused him to double up. It was impossible to obtain any history of previous indigestion until after operation, when it was learned that, for one week before admission, he had experienced gnawing, cramp-like pain of moderate severity in the region of the umbilicus. The pain usually began between 3 and 4 P. M. each day and lasted three hours. It was accompanied by anorexia and

slight nausea but no vomiting. He ate no evening meal for the whole week. The pain was not relieved by food.

The past history was irrelevant.

The leukocytes were 13,240 with 86% polynuclears. The blood pressure was 118/90.

Physical examination showed a young, white boy lying in bed, suffering severe pain, with both thighs flexed. The abdominal muscles were spastic throughout, with board-like rigidity in both upper quadrants. There was also extreme tenderness—most marked in the epigastric region.

The liver dulness was completely obliterated.

An operation was performed two and one-half hours after onset of symptoms—by Dr. Henry F.

Graham. A small, soft, pin-head sized perforation was found one inch from the pylorus on the duodenal side. The perforation was sutured, an omental graft applied, and a posterior no-loop gastro-enterostomy performed. The patient made a rapid convalescence except for an infection of the wound which separated and required secondary suturing on the 13th day after operation with resulting prompt union.

On the day of discharge, 30 days post-op., a fluoroscopy showed a well-functioning gastro-enterostomy with equal portions of the contrast media passing through the pylorus and the enterostomy. For the first three weeks after leaving the hospital, he had a constant, vague pain in the epigastrium, not related to meals, but since then has been symptom free on a restricted meat diet.

The age incidence study has chiefly attracted our interest in this case. McCarty states that "acute perforation is essentially a condition of young adult life. Half of the cases are found between the ages of twenty and thirty; and three-fourths, before the age of forty." It seems to be the impression of earlier writers that ruptured peptic ulcers occur in young adult life. A review of the literature and our own series of cases would indicate that this condition occurs more commonly at a much later age.

Dineen reporting 142 cases of acute perforated ulcer of the stomach and duodenum from the New York Hospital, states that the youngest patient was eighteen years old and the oldest sixty-nine.

Morrison states that in fifty cases of perforated gastric and duodenal ulcer the age of the patient varied from twenty-three to seventy-two years.

Brown reported 100 cases of perforated peptic ulcer from the Pennsylvania and Presbyterian Hospitals in Philadelphia, and, in his series, two patients were under the age of twenty; twentysix, between twenty and thirty years; twentyseven, between thirty and forty years; seventeen, between forty and fifty years; seventeen, between fifty and sixty years; seven, over sixty; and, in four cases, the age is not stated.

Dunbar, in a review of 387 cases of perforated ulcer from the Glasgow (Scotland) Royal Infirmary, states that 6 per cent were under twenty years of age; 21.9 per cent, between twenty and

thirty; 29.2 per cent, between thirty and forty; 20.6 per cent, between forty and fifty; 17.2 per cent, between fifty and sixty; 4.7 per cent, over sixty. The youngest patient in his series was a boy twelve years of age; the oldest, a man of seventy-four years of age.

Hearst and Stewart, in their publication in 1929 on gastric and duodenal ulcer, give the most common age incidence as 25-45 years—males perforating on the average at 48.7 years and females at 41.8 years. They also cite Moynihan's fatal case at 77 years and Butka's case on the 4th day after birth.

In the Methodist Hospital, since 1920, there have been sixty-six cases of perforated peptic ulcer. The youngest case in our series was 18 years of age; the oldest, 76 years of age. According to age, they ranged as follows:

Below 20 years	2 c	ases	(both	18	years)
20-29 "	16	"			-
3039 "	19	"			
40-49 "	15	"			
50—59"	10	"			
6069 "	3	"			
Above 70 "	1	"	(age	76	years)

Average age in this series was 38.7 years.

Only 27.2 per cent perforated before the age of 30 years.

Only 56 per cent perforated before the age of 40 years.

28.7 per cent (19 cases) occurred between the ages of 30-39 years.

## Conclusions:

- (1) Perforated peptic ulcer is rare under the age of twenty, and the more recent analyses of cases indicate that the average age incidence is higher than formerly supposed. In our own series of cases, the average was 38.7 years.
- (2) A gastro-enterostomy is performed on this Service at the time of the suturing of the perforation on all good operative risks.
- (3) We are impressed by the rather frequent absence of an ulcer history at the time of rupture. After the relief of the acute symptoms, such a history is then frequently obtained.

Annual meeting June 2-4, 1930, Hotel Seneca, Rochester, N. Y.

### ANNUAL MEETING

The expansion of the activities of the Medical Society of the State of New York becomes evident when one considers the extensiveness of the preparations for the annual meeting on June 2 to 4 in Rochester. Seventy pages of the Journals of April fifteenth, May first and May fifteenth are on the annual meeting including the annual reports of the officers and committees, and the personnel of the References Com-

mittees who will consider the reports and suggest the action which the House of Delegates should take.

This issue of the Journal contains the final announcements of the plans of the local Committee on Arrangements for the care and entertainment of the attending physicians and their wives. Let there be a good attendance at the annual meeting.

## CENTERS, MEDICAL AND HEALTH

A characteristic of modern medicine is the influence of the group of physicians upon the individual doctor. Each individual physician who works in close association with others contributes his experience to a common fund of knowledge, and draws from it the wisdom and inspiration of the others. Any medical organization which influences its individual members is a medical center. Its teaching may not be done along formal and didactic lines, but, nevertheless, its quiet influence is a most potent power in promoting medical progress and good practice.

There are medical centers and there are health centers, and the two are distinct from each other.

A medical center is purely medical, and its dominance by physicians is unquestioned. It exists for the detection and treatment of diseases and defects, and almost its entire equipment and administration are directly subservient to the physicians who belong to it.

A health center is concerned principally with the prevention of sickness. Its work is largely educational and social, and its staff consists principally of public health nurses and other non-medical workers; but physicians are absolutely necessary, for it is on their diagnoses and suggestions that the nurses, social workers, and teachers act.

A medical center has for one great object the continuous education of physicians in the art of medical practice. It exemplifies the collective influence of the group of physicians upon the individual member of the staff. The attending physicians and surgeons have widedifferent temperaments and tendencies, varying from intense individualism to altruism and broad cooperation. The doctor connected with a medical center is necessarily subjected to the influence of the best standards of the group, both in his attainments and in his conduct.

A health center exists primarily for the health education of the people along preventive lines. It deals with those facts of scientific medicine which may be applied by the people themselves. It teaches mothers to feed their babies; to bring them for preventive inoculations; and to heed the first signs of sickness.

A health center also teaches physicians how to deal with patients who are in comparatively excellent health. Almost any doctor can render first-class emergency service to a patient who is helpless; but it requires quite another approach to influence a well person or a mother of a husky baby. A health center educates the doctor as well as the patient.

Medical centers are composed of three principal elements:

- 1. Public Hospitals.
- 2. Medical Societies.
- 3. Medical Schools.

Every public hospital is a center of medical influence upon the members of its staff. The standards of public hospitals have been developed spontaneously by the members of their staffs organized as the national body called the American College of Surgeons. The essential elements of the standards are educational along two lines:

1. Written records of every patient, both

public and private.

2. Regular meetings of the members of the

staff for the discussion of any case.

The results of the universal adoption of the hospital system have been wide-spread in causing every member of the staff to adopt the hospital standards in his private practice. It has also educated the people to judge good medical service from poor; and it has inspired them to provide the equipment which will enable the doctors to practice a high standard of medicine.

Not every doctor is on a medical staff of a hospital; and not every staff member deserves a rating of one hundred per cent in his conformity to the ideals of the center. But every active physician comes into frequent contact with some hospital and is subjected to the quiet influence of the medical center.

Every Medical Society and Academy of Medicine is a medical center which has a deep and lasting influence upon the practice of medicine by its individual members. While few societies own or control their own buildings or suites of offices, yet their influence is profound in developing methods of dealing with the public. If, for example, the members of a board of county officials are considering the establishment of a nursing service, the County Medical Society is the natural center to which they should go for information and advice. On the other hand, it is the County Society which should be the center from which all these public health movements originate—and a constantly increasing number of county societies are assuming such leadership.

County Medical Societies provide physicians with the means by which they can discharge their duties to the community along civic lines; while a hospital enables them to discharge their individual duties to individual persons.

Every Medical School is also a medical center, not only to the medical students, but also to the physicians of its community. The modern medical school has bridged the great gulf that formerly existed between the undergraduate students and the teachers; and it now promotes a comradeship between teacher and pupil. The fourth year of study is largely a year of interneship, while the fifth and sixth years bring the medical leaders into intimate contact with the learners as they study their cases and work out their problems in a spirit of mutual helpfulness. Medical students teach their teachers as they delve into text-books, and ask disconcerting questions.

Health centers also have a prominent place in the system of medical education, for the practice of medicine will go no further than the people will allow. While medical science is able to point the way to the prevention or cure of most human ailments, yet men and women do not know about the methods, or are unwilling or unable to apply them. The existence of a health center with rooms and displays proclaims the availability of medical serv-

ice to all people.

While this is an age of organizations and groups, yet the American people, including the doctors, are essentially individualistic in their habits of thought and their methods of action. The people like to speak of "my doctor," and the physicians like to speak of "my patient." The ideal toward which the private practice of medicine is rapidly moving is that every doctor shall be a health center as well as a medical center to his patients. The Department of Health of New York City is emphasizing this ideal in its daily bulletins to the doctors and to the people. The Medical Society of the State of New York is urging its members to extend their practice to the preclinical and preventive stages of diseases, thereby compensating themselves for the loss of practice in diseases which have become almost extinct through the efficiency of their service.

Centers of medicine and health have sprung up separately from one another, each group developing its own organization. But there are premonitory stirrings of the birth of a unified system of medical and health centers which shall include hospitals, medical societies, medical schools, and health centers. Such a system is proposed for Brooklyn. The plan embraces the following points:

1. New buildings for the Medical School of the Long Island College Hospital and its separation from the administration of the Hos-

pital.

2. Coordination and cooperation with the Kings County Medical Society and the housing of the Society and its extensive library in the new buildings of the Medical School.

3. The affiliation of the Medical School with nine of the leading hospitals of Brooklyn.

4. Finally there will naturally follow the absorption of health centers into the coordinated system of leadership in medical service.

Brooklyn is the natural place for the establishment of a unified system of medical centers. While it is now the most populous borough of Greater New York, yet its growth has been that of a residential village adjoining commercial Manhattan. Brooklyn still retains many of the desirable characteristics which it developed a century ago while it was a series of small villages separated by farms. Physicians, hospitals and the County Medical Society are ready to cooperate in the plan of unification. The success of the proposed medical center depends on securing an endowment worthy of the undertaking.

## LOOKING BACKWARD

## This Journal Twenty-Five Years Ago

Spitting in Public:—Spitting in public places is not nearly so prevalent as it was a quarter of a century ago, when prohibitory signs were everywhere, and spittoons were common articles of furniture. This Journal of May, 1905, contained the following letter somewhat in defense of the practice:

"The position of our Board of Health in regard to the spitting nuisance, while admirable in its purpose, does not seem to be practicable. The great danger to the community of promiscuous spitting is a matter of common knowledge to every well-informed individual, but to demand that no one shall expectorate except in the privacy of his own house, or into a sputum cup which he carries about with him, is to ask more than is reasonable, or at least more than will be granter

"Many of our citizens are suffering from catarrhal conditions of the nasopharynx, larynx and bronchi, of varying degrees of severity, which render spitting necessary. To swallow the expectoration as women commonly do is to say the least of questionable desirability.

"What shall we do with the man who smokes? Shall we forbid him to smoke on the street, or require that the saliva saturated with the juices of tobacco be swallowed?

"Why not meet the need sensibly, and provide at the center or corner of each block some suitable receptacle containing an antiseptic solution and then insist on the strict enforcement of the Board of Health ruling. If this were done there would be some prospect of prevent-

## CENTERS, MEDICAL AND HEALTH

A characteristic of modern medicine is the influence of the group of physicians upon the individual doctor. Each individual physician who works in close association with others contributes his experience to a common fund of knowledge, and draws from it the wisdom and inspiration of the others. Any medical organization which influences its individual members is a medical center. Its teaching may not be done along formal and didactic lines, but, nevertheless, its quiet influence is a most potent power in promoting medical progress and good practice.

There are medical centers and there are health centers, and the two are distinct from each other.

A medical center is purely medical, and its dominance by physicians is unquestioned. exists for the detection and treatment of diseases and defects, and almost its entire equipment and administration are directly subservient to the physicians who belong to it.

A health center is concerned principally with the prevention of sickness. Its work is largely educational and social, and its staff consists principally of public health nurses and other non-medical workers; but physicians are absolutely necessary, for it is on their diagnoses and suggestions that the nurses, social workers, and teachers act.

A medical center has for one great object the continuous education of physicians in the art of medical practice. It exemplifies the collective influence of the group of physicians upon the individual member of the staff. The attending physicians and surgeons have widely different temperaments and tendencies, varying from intense individualism to altruism and broad cooperation. The doctor connected with a medical center is necessarily subjected to the influence of the best standards of the group, both in his attainments and in his conduct.

A health center exists primarily for the health education of the people along preventive lines. It deals with those facts of scientific medicine which may be applied by the people themselves. It teaches mothers to feed their babies; to bring them for preventive inoculations; and to heed the first signs of sickness.

A health center also teaches physicians how to deal with patients who are in comparatively excellent health. Almost any doctor can render first-class emergency service to a patient who is helpless; but it requires quite another approach to influence a well person or a mother of a husky baby. A health center educates the doctor as well as the patient.

Medical centers are composed of three principal elements:

- 1. Public Hospitals.
- 2. Medical Societies.
- 3. Medical Schools.

Every public hospital is a center of medical influence upon the members of its staff. The standards of public hospitals have been developed spontaneously by the members of their staffs organized as the national body called the American College of Surgeons. The essential elements of the standards are educational along two lines:

1. Written records of every patient, both

public and private.

2. Regular meetings of the members of the

staff for the discussion of any case.

The results of the universal adoption of the hospital system have been wide-spread in causing every member of the staff to adopt the hospital standards in his private practice. It has also educated the people to judge good medical service from poor; and it has inspired them to provide the equipment which will enable the doctors to practice a high standard of medicine.

Not every doctor is on a medical staff of a hospital; and not every staff member deserves a rating of one hundred per cent in his conformity to the ideals of the center. But every active physician comes into frequent contact with some hospital and is subjected to the quiet influence of the medical center.

Every Medical Society and Academy of Medicine is a medical center which has a deep and lasting influence upon the practice of medicine by its individual members. While few societies own or control their own buildings or suites of offices, yet their influence is profound in developing methods of dealing with the public. If, for example, the members of a board of county officials are considering the establishment of a nursing service, the County Medical Society is the natural center to which they should go for information and advice. On the other hand, it is the County Society which should be the center from which all these public health movements originate—and a constantly increasing number of county societies are assuming such leadership.

County Medical Societies provide physicians with the means by which they can discharge their duties to the community along civic lines; while a hospital enables them to discharge their individual duties to individual persons.

Every Medical School is also a medical center, not only to the medical students, but also to the physicians of its community. The modern medical school has bridged the great gulf that formerly existed between the undergrad-

through stewing (93 per cent.). Moreover analyses of the mineral content of vegetables shows much natural variation in individual specimens. Another element is the relative proportion between basic and acid equivalents. Experiments in boiling vegetables in plain water shows us that addition of 1 per cent. cooking salt tends to prevent much of the waste of mineral matter. Moreover a so called transmineralization is also effected. The wide spread, almost universal use of salt in cooking, probably over many millenia, is therefore founded on a sure instinct. Other substances like calcium chloride used in cooking might exert a like effect. In regard to basic and acid components the neutralization by the general economy is not dependent on the relative amounts in the ash of the food. We do not know yet that by ordinary dieting we can increase the acid component although this belief was held by some of the old biochemists and still obtains to some extent, being based on the fact that potassium can drive sodium out of the tissues. The cells take what they need irrespective of the dietetic ration .-Schweizerische medizinische Wochenschrift, March 8, 1930.

The Relation of Intestinal Toxemia to Allergy.-In support of his belief that there is a definite relation between intestinal toxemia and allergy, Allan Eustis quotes from an editorial in the Journal of the American Medical Association in which the statement is made that intestinal allergy at best accounts for only a fraction of the cases of allergy that come under observation, and in which reference is made to a study of 1,000 cases of asthma in less than half of which did the condition show any relation to an intrinsic antigen. In a former study of 178 cases of asthma, Eustis found that only 1.7 per cent, failed to give a strong indican reaction, which is evidence of intestinal toxemia, while only 5.6 per cent, were not benefited by therapy directed to the intes-tinal condition. His routine treatment consists in relieving the acute symptoms by hypodermic administration of ephedrine or epinephrine, and a thorough evacuation of the intestinal tract by means of calomel, phenolphthalein, and rhubarb. A tablespoonful of syrup of hydriodic acid is given every two hours until the bronchial secretions are softened, and a large amount of fluid is ingested, and 36 to 34 of a grain of ephedrine sulphate is given every three or four hours. The patient is kept on a cereal, fruit, and vegetable diet, excluding peas and beans, until the urine shows a negative reaction for indican. Cream is allowed on cereals and in coffee, but no milk, twenty-four hours the patient in iy in symptoms and the urine is ind dophilus buttermilk is now added three days, then per

eggs. The indican test is the guide as to the allowance of animal protein. The results of this treatment are uniformly good. Eustis does not claim that intestinal toxemia is the cause of asthma or urticaria, but he urges a consideration of the influence of intestinal toxemia on these conditions, and says that the gastroenterologist is in a position to assist in the treatment of these cases.—Southern Medical Journal, April, 1930, xxiii, 4.

Acute Appendicitis in the Aged .-- H. Flörcken and R. Riemann emphasize the relative infrequency of this association, which is due chiefly to involutional changes which affect the appendix after middle life. An average of some 80 per cent. of all individuals undergo these changes, which agrees in a way with the fact that less than 10 per cent, of all cases of acute appendicitis develop after the age of 50. In the aged, men are more frequently attacked than women. The temperature is strikingly low even in perforative cases and purulent peritonitis. The pulse is between Vomiting, found in 15 per cent, 80 and 90. occurred only when peritonitis had developed. The leucocytosis is about 15,000 in the perforative type but in diffuse purulent peritonitis may reach 40,000. Of 145 cases in patients between 50 and 80 over half gave typical local signs while no less than 63 were atypical and the frequent cause of erroneous diagnosis. Thus in 9 cases the diagnosis was intestinal obstruction, in 18 malignant neoplasm in the cecum, while in no less than 35 the symptoms pointed to purulent cholecystitis. The mortality was 12.4 per cent., death being due to peritonitis or embolism of the lungs. There was interference with the intestinal functions, a feeling of fulness in the belly and pressure pains over the appendix. The operative risk is enhanced in the elderly and at times the surgeon may get along with local or lumbar anesthesia or with gas anesthesia. In general the prognosis is more unfavorable with ether, and the earlier the operation the better the chance of light anesthesia. In the differential diagnosis of obscure acute abdominal disease one should not overlook the possibility of appendicitis, despite the infrequency and the misleading character of the symptoms .- Deutsche medizinische Wochenschrift, March 14, 1930.

Premonitory Signs of Crises of Chronic Colitis.—G. Faroy and H. Deseille refer to any kind of chronic colitis, mucous, muco-membranous, spastic, etc., although presumably the ulcerative form is excluded. While many patients do not complain during the intervals, others present well marked symptom pictures within 24 to 48 hours preceding acute crises. In some patients only one or a few symptoms may be in evidence. The authors give six semciological categories—ocular, nasopharynsemciological categories—ocular, nasopharynsemciological categories—cardiac, and urinary.

The first named comprise blepharitis with or without conjunctivitis or there may be only a There may be a profuse discharge from the nose, serous and without any suggestion of a cold in the head or other intranasal affection, and in some cases a spasmodic coryza. Nervous manifestations are subjective -fatigue with myalgia and especially lumbalgia, vertigo, insomnia. Digestive symptoms are numerous, comprising intense thirst, bulimia, false hunger, occurring without respect to need of food, pyrosis, air hunger, sialorrhea, etc. Of cardiac disorders the authors mention tachycardia, extrasystoles and bradycardia, and of urinary symptoms a transitory polyuria which may stand in some relationship to the thirst above mentioned. These various manifestations are well known to gastroenterologists and the authors quote freely from their writings. An attempt is made to account for the genesis of these symptoms but the authors can do little more than implicate fecal retention, which is so marked in these patients, and a quasi-toxic action on the vegetative nervous system. Twenty years ago Bonnier sought to trace a reflex between the colon and the trigeminal region and it is possible that certain of the symptoms have this reflex spinobulbar mechanism. In some symptoms there is a suggestion of anaphylactic mechanism, in which the offending substance is a protein absorbed from the intestine.—Le Progrès Médical, March 22, 1930.

Collodion Treatment of Boils and Carbuncles.—Walter J. Robbins states that the difference between boils and carbuncles is size. Other things being equal, the more compact the tissue, the greater the resistance to the extension of infection. The surrounding tissue can be rendered more compact by making use of the contractile power of collodion. The collodion must be contractile, i.e., collodion, The skin should be shaved, and if an ointment has been used, this must be removed by washing with gasoline. The final cleansing of the skin should be with alcohol or ether, or preferably both. The collodion is painted in a thick circular band around and on the boil. leaving an opening where it seems to be pointing, or where it is desirable that it should discharge. The band should be wide enough to extend beyond all inflamed tissue. It should be thick in the middle and tapering toward the periphery and toward the central opening. build a thick layer, the collodion should be applied by from ten to twenty circular strokes with a saturated swab. The size varies from a diameter of 11/2 inches with a 1/4 inch opening for a small boil to an area with diameter of 6 or 8 inches for a carbuncle. The pain is re-Reved within thirty seconds and does not recur. Wrinkles appear in the collodion and on the surrounding skin, showing that the tissue

is being pulled together, and there is considerable projection of tissue through the central opening. In from twenty-four to forty-eight hours the central projection breaks down and the slough is discharged. The collodion is covered with a gauze dressing secured by adhesive strips. For a boil near the edge of the lip, the collodion is applied in a half circle. The advantages of this treatment are prompt relief of pain, no need for incision, protection of the surrounding skin so that there is no secondary crop of boils, prompt discharge of the slough, and entire compatibility with other methods of treatment.—American Journal of Surgery, February, 1930, viii, 2.

Thyroxin in Eclampsia.—Professor H. Küstner of the Sellheim Gynecological Clinic, who recently made a favorable report on this subject, makes a second contribution on the occasion of a criticism recently published by Hammerschlag. Since his first report he has had four more cases of manifest eclampsia which he relates briefly and which do not include a considerable series of cases of threatened eclampsia. The first patient had had four attacks of convulsions seen by the family physician. The fetus was apparently dead in utero on admission to the clinic. For two days the patient received only a single dose of thyroxin and one of morphine the attacks in the meantime ceasing. Labor was then induced with birth of a macerated fetus. The second case was similar, but the child was evidently alive and labor was induced with the birth of a living child. Although seizures had ceased one occurred during delivery. The third case was also analogous to the preceding but labor set in spontaneously, and the fourth was of the same type. The four mothers recovered under no other treatment than a single injection of 2 mg, of thyroxin. The criticism of Hammerschlag had reference to a possible unfavorable action on the fetus, but the author is able to show in the above series that the only fetal death had preceded admission to the clinic. This criticism is founded in part on some animal experiments in which thyroxin appears to have caused abortion. The action of the drug in pre-eclampsia is salutary and the author has reached the conclusion that thyroxin deserves the status of a principal remedy and not a mere auxiliary in eclampsia. In the first case in which the fetus was dead, the death must be given some credit for the recovery, as there can be no doubt that this accident is for the advantage of the mother.-Klinische Wochenschrift. March 22, 1930.

Therapeutic Application of the Parathyroid Hormone.—Karl Hajós of Koranyi's Internist Clinic, Budapest, refers briefly to a series of results reported to date by others and then submits some of his own. First he has treated a

group of renal cases, subacute and chronic, and classed under both nephritis and nephrosis Collip and others claim that the hormone mobilizes lime from the tissues to the blood and have added lime salts to offset the overaction of the same As the lime saits have no deleterious action on the kidneys the author has followed this precedent in the renal series. He gives a brief sketch of 6 cases mostly of severe Of these two with uremia succumbed with no benefit from the treatment. One with pre uremia showed steady improvement as did A fifth with another with marked oliguria oliguria did not improve, while the sixth, which was apparently not far advanced, showed bene-The records show that the hormone is without influence on diuresis and blood pressure nor does it reduce the residual nitrogen In two cases, not included, the latter was even increased and it was thought best to decapsulate the kidneys The patients who most improved under the hormone had a low residual nitrogen with marked subjective symptoms and it is in this group that it appears to be chiefly indicated No rationale of its action in these cases is stated. The next group of cases in which it was tried out was of allergic diseases, comprising bronchial asthma, hay fever, and urticaria including Quincke's disease In some of the cases the results were strikingly good-much more impressive than those in the renal series Although lime salts were added to prevent hyperparathy roidism they cannot be credited with any of the improvement obtained for they were given alone before beginning the hormone treatment Other affections in which the hormone should be useful, are tetany, spasmophilia hemorrhagic drithesis, etc -Deutsche medizimsche Wochenschrift, March 21, 1930

Thallium Acetate as a Depilatory in Ringworm of the Scalp -H McCormick Mitchell, after pointing out the disadvantages of x-ray treatment of ringworm of the scalp, most serious of which is the permanent baldness which sometimes follows, relates his experience with thallium acetate In a series of 75 children with ringworm of the scalp 65 were cured after one dose of the drug In 10 cases the hairs were reinfected after growth, and a second dose was necessary It is also notable that most of the failures were where a dose of only 8 mg of thallium acetate per kilo of body weight was administered. The routine plan of treatment is as follows. The urine is examined for albumin and casts, and 85 or 9 mg of thallium acetate per kilo of body weight is given in a little sweetened water or mixed with food Starting the next day, the scalp should be washed daily with spiritus saponis kalinus, or with 10 per cide ointment v

begins to fall, to ointment are us toxic symptoms were not observed in this series of cases This the author attributes to the fact that he insists upon all patients remaining in bed for forty eight hours after the thallium acetate has been administered Careful examination with the ultraviolet beam should be made after epilation is apparently complete, so as to detect any infected stumps, and these should be removed to prevent infection of the new growth of hair Children with dark hair are more difficult to depilate than those with fair hair, the former class should, therefore, receive 9 mg of thallium acetate per kilo hairs on the crown fall out less readily than those on other parts of the scalp, for ringworm in this situation it is better to give the full 9 mg dose The use of thallium acctate should, as far as possible, be limited to children under the age of 5, owing to its toxic effect upon those above that age -British Medical Journal, March 29, 1930, 1, 3612

The Heart and the General Practitioner -George D Hale formulates a set of office rules for the simple office examination of the heart which, when followed, will afford the minimum number of disasters Sinus arrhythmia and extrasystole do not indicate organic heart dis-Physiological bradycardia and paroxysmal tachycardia are of no importance, but auricular flutter indicates organic heart disease Lacking evidence of cardiac enlargement or other signs of organic heart disease, a sys tolic murmur may be disregarded A diastolic murmur always means heart disease, probably my ocardial degeneration Enlargement of the heart always means disease of the cardiovascular system It is important to remember that it is the abnormal facility with which symptoms are produced rather than the symptoms themselves that is important. In testing for response to effort one should not tie oneself to so many "foot minutes-pounds," but the patient should be put through such exercise as is suited to the severity of the case. If given a group of patients with suspected cardiac disease, the best procedure to follow is to place in the list of suspected or proved cases of orgame cardiac disease those with (1) A history of acute rheumatic fever, or of any severe infection definitely antedating the appearance of the cardine symptoms, (2) a diastolic murmur, (3) enlargement of the heart, (4) evidence of hyperthyroidism, (5) pain of anginal distribution, (6) a pulse of irregular irregularity with the rhythm not improved by exercise (7) an abnormally rapid or slow pulse, (8) evidence of venous congestion, (9) a positive Wassermann test, high blood pressure, or urine of low and fixed specific gravity. The based

## ATTORNEYS, COURTS INHERENT POWER OF DISCIPLINE

By LORENZ J. BROSNAN, ESQ. Counsel, Medical Society of the State of New York

One of the most salutary movements ever initiated by members of the Bar took place in the City of New York in January of 1928, when the three leading Bar Associations of the City of New York united in petitioning the Appellate Division to take disciplinary measures in connection with the gross abuse incident to "ambulance chasing." For a long time prior to 1928 both Bench and Bar were aware of the scandalous conditions existing in personal injury cases. The evils are tersely but graphically described by Chief Judge Cardozo in one of his opinions, where he said:

"'Ambulance chasing' was spreading to a demoralizing extent. As a consequence, the poor were oppressed and the ignorant overreached. Retainers, often on extravagant terms, were solicited and paid for. Calendars became congested through litigations maintained without probable cause as weapons of extortion. Wrongdoing by lawyers for claimants was accompanied by other wrongdoing, almost as pernicious, by lawyers for defendants. The helpless and the ignorant were made to throw their rights away as the result of inadequate settlements or fraudulent releases."

In pursuance of the petition above referred to, the Appellate Division appointed Mr. Justice Wasservogel to conduct an exhaustive investigation of the entire situation. Mr. Justice Wasservogel immediately entered upon his duties, and was assisted in the investigation by some of the leading members of the Bar who served without compensation. It is pleasing to be able to state that when the investigation was finished and Mr. Justice Wasservogel filed his report, he took occasion to point out that the Bar as a whole was honest, but that the honest members of the Bar had suffered in the past by reason of the unscrupulous tactics of the few who had been unfaithful to their obligations as members of the Bar:

The investigation had not proceeded far when its legality was challenged by a member of the Bar who had been subpænæd to give evidence before the judge conducting the inquiry. This man had been a lawyer for twenty-five years and his practice had involved the trial of many actions for personal injuries on the plaintiff's side. He was called to testify as to his conduct in the procurement of retainers in these cases and in others. He appeared in court but refused to be sworn, claiming that the entire proceeding was

unauthorized and unconstitutional. The court adjudged him in contempt and committed him to jail until he should submit to be sworn and examined. He then sued out a writ of habeas corpus, but the writ was dismissed by the court. From both orders, i.e., the one adjudging him in contempt and the one dismissing the writ, an appeal was taken to the Appellate Division where they were affirmed. A further appeal was then taken to the Court of Appeals. The precise question presented to the Court of Appeals for decision was whether there is power in the Appellate Division to direct a general inquiry into the conduct of its own officers, the members of the Bar. and in the course of that inquiry to compel one of those officers to testify as to his acts in his professional relations. The importance of the question thus presented to the Court of Appeals cannot be underestimated. Indeed the continuance of the entire ambulance chasing investigation hung upon the Court of Appeals' decision on this question. In an epoch-making decision of far-reaching importance the Court of Appeals unanimously sustained the right of the Appellate Division to compel the members of the Bar to testify in the ambulance chasing investigation. The court spoke through its Chief Judge Benjamin N. Cardozo, who said in rendering the opinion of the court:

"'Membership in the bar is a privilege burdened with conditions.' \* \* The appellant was received into that ancient fellowship for something more than private gain. He became an officer of the court, and, like the court itself, an instrument or agency to advance the ends of justice. His cooperation with the court was due whenever justice would be imperiled if cooperation were withheld. He might be assigned as counsel for the needy, in causes criminal or civil, serving without pay. \* \*

He might be directed by summary order to make restitution to a client of moneys or other property wrongfully withheld. \* \* He might be censured, suspended or disbarred for 'any conduct prejudicial to the administration of justice.' \* \* All this is undisputed. We are now asked to hold that when evil practices are rife to the dishonor of the profession, he may not be compelled by rule or order of the court, whose officer he is, to say what he knows of them, subject to his claim of privilege if the answer will expose him to punishment for crime. \* \*

Cooperation between court and officer in furtherance of justice is a phrase without reality if the officer may then be silent in the face of a command to speak. There are precedents of recent date, decisions in Wisconsin and Ohio, upholding the power of the Court by a general inquisition to compel disclosure of the truth. \*\* Precedents far more ancient, their roots deeply set in the very nature of a lawyer's function, point the same way.

'The supreme court shall have power and control over attorneys and counselors-at-law.' \* \* The first Constitution of the State declared a like rule in terms not widely different. Provision was there made that 'all attorneys, solicitors and counselors-at-law hereafter to be appointed, be appointed by the court and licensed by the first judge of the court in which they shall respectively plead or practice; and be regulated by the rules and orders of the said courts.' \* \* What was meant by this provision that lawyers should be 'regulated by the rules and orders of the said Would the men who framed the Constitution of 1777 have been in doubt for a moment that a rule or order might be made whereby lawyers would be under a duty, when so directed by the court, to give aid by their testimony in uncovering abuses? We find the answer to these questions when we view the history of the profession in its home across the seas.

Judge Cardozo then proceeded to show that from the earliest times the English Courts had powers of discipline over the barristers that prac-

tice before them.

It is only plain common sense, as the court pointed out, that the power to inquire carries with it by fair implication the power to compel a witness to testify as to facts that he has knowledge of. As the court said, it would be "a curious anomaly if the courts with all their writs and processes could do less in regulating and controlling the conduct of their officers than a legislative body can do in relation to a stranger." It was argued before the Court of Appeals by the counsel for the lawyer who had been held in contempt, that the reputation of the members of the Bar would be in danger if this proceeding were held to be legal. The court answered this argument in the following language:

"The argument is pressed that in conceding to the court a power of inquisition we put into its hands a weapon whereby the fair fame of a lawyer, however innocent of wrong, is at the mercy of the tongue of ignorance or malice. Reputation in such a calling is a plant of tender growth, and its bloom, once lost, is not easily restored. The merc summons to appear at such a hearing and make report as to one's conduct, may become a slur and a reproach. Dangers are indeed here, but not without a remedy. The remedy is to make the inquisition a secret one in its preliminary stages. This has

instances, by the order of the justice presiding at the hearing. It has been done in the second judicial department, where a like investigation is in progress, \* \* by order of the Appellate Division directing the inquiry. A preliminary inquisition, without adversary parties, neither ending in any decree nor establishing any right, is not a sitting of a court within the fair intendment of section 4 of the Judiciary Law whereby sittings of a court are required to be public. It is a quasi-administrative remedy whereby the court is given information that may move it to other acts thereafter. \* \* The closest analogue is an inquisition by the grand jury for the discovery of crime. There secrecy of counsel is enjoined upon the jurors by an oath of ancient lineage. Full protection against publicity was accorded to the relator if he had chosen to avail of it. Publicity came to him through his refusal to be sworn.

The court then held that the refusal of the lawyer to answer was a contempt, and Judge Cardozo concluded his opinion with a statement with which every honest lawyer is heartily in accord:

"We conclude that the refusal was a contempt, \* \* and that the investigation must proceed. In so holding we place power and responsibility where in reason they should be. No doubt the power can be abused, but that is true of power generally. In discharging a function so responsible and delicate, the courts will refrain, we may be sure, from a surveillance of the profession that would be merely odious or arbitrary. They will act considerately and cautiously, mindful at all times of the dignity of the Bar and of the resentment certain to be engendered by any tyrannous intervention. No lack of caution or consideration can be imputed to them here. They did not move of their own prompting, but at the instance of the very Bar whose privacy and privilege they are said to have infringed. In the long run the power now conceded will make for the health and honor of the profession and for the protection of the public. If the house is to be cleaned, it is for those who occupy and govern it, rather than for strangers, to do the noisome work."

By this momentous decision the ambulance chasing inquiry was permitted to continue to a successful conclusion. The salutary effect of the investigation has been seen by every practicing lawyer in the City of New York. It has proved to be an effective deterrent to members of the Bar who might be inclined to violate their oath of office. It has resulted in the disbarment, suspension and censure of a number of attorneys whose activities in the field of ambulance chasing were exposed during the investigation. It has succeeded in ridding the profession of men who demonstrated by their professional life that they did not possess those ethical and moral qualifications which should be possessed by those who aspire to membership in a learned and honorable

profession.

# LONDON LETTER

Knights of the Round Table: The American Ambassador to the Court of St. James suffer many must functions and endure many banquets during his tenure of office. and it may well have been with a feeling of relief that he accepted the invitation to dine with the Knights of the Round Table. I can imagine him saying, "Whoever these people are, and I am sure I have no idea who they are, at least they will not expect me to talk international politics." And so it proved, for when he replied to the toast of his health and that of the Naval delegates he spoke not of the smaller matters of everyday concern but of high ideals, of chivalry, and of that great faith for which King Arthur fought and died so many years ago. How comes it that this Club, founded 210 years ago, and having apparently no functions save that of extolling the ideals of chivalry as exemplified at King Arthur's Court, should have survived the constant changes of social usage and be to-day stronger and more active than at any time in its history? Originally founded by sixteen Arthurian devotees it quickly enrolled the one hundred and one "knights" which composed the Round Table, and though it has increased its membership to 150, admission to the circle is closely guarded, and over 300 are on the waiting list. Members of all the liberal professions are included in their numbers and many a famous name has figured on the roll of membership. In June a pilgrimage takes place to Winchester, the old capital town of the West Saxons, when the Club is received by the Mayor of the City and a luncheon is held where the memory of King Arthur and his Knights is proclaimed by King Arthur's Champion. I cannot doubt that such an assembly as I was privileged to attend would have delighted the great hero and relieved the doubt so beautifully expressed by Tennyson in the Morte D'Arthur:

"The sequel of to-day unsolders all
The goodliest fellowship of famous knights
Whereof this world holds record. Such a sleep
They sleep—the men I loved. I think that we
Shall never more, at any future time
Delight our souls with talk of knightly deeds,
Walking about the gardens and the halls
Of Camelot, as in the days that were."

The Registrar-General's Report: trar-General's returns for 1929 once more point out that the steady fall in the birthrate, which has been in evidence of recent years, is still operative, and that in 1929 the birth-rate was 0.4 per 1,000 below 1928 which was the lowest on record. This lower birthrate coupled with a death-rate increase of 1.7 per 1,000 over 1928 owing to the influenza epidemic and the severe weather last spring, has reduced the increase of population from an average of 221,000 to 111,693. Of course, these figures represent an unusually bad year, but a steady fall in the birth-rate must always be a matter of concern. So many causes combine to affect the birth-rate that it is difficult to estimate their relative importance and in turn the housing problem, birh control, the cost of living leading to late marriages, and many other factors have been blamed. For us, living in a small island which is already overpopulated, the problem may seem to present compensations, but inevitably with an expectation of life at its present high level a time must come when the population will remain stationary and then begin to decline. The decline of the birth-rate is not confined to England, but is occurring in all the white races, and its cause and cure should be a leading preoccupation for sociologists of all nations.

Fashion: That Fashion is a tyrant to whom we all must bow is perhaps a truism. One must admit there are a few fine characters like myself whose refusal to vary the cut of their clothing every few months is the despair of our tailors (stout fellows we call ourselves, but are known as old fogies by the undiscerning), but in what we superciliously call the weaker sex the tendency to yield to some mysterious authority and to adopt a costume which makes them all look exactly alike is very noticeable. A few days ago in the children's ward of my Hospital a little girl of 6 years was admitted with an injury to the eye necessitating the use of a bandage. In the cots near her were three or four mastoid cases, and one morning the ward sister discovered that our young disciple of Fashion had removed the bandage from her eye and adjusted it over her ear. We are reminded of Goldsmith's "Deserted Village":

"And e'en while fashion's brightest arts decoy The heart distrusting asks if this be joy."

H. W. Carson, F.R.C.S.

# NEWS NOTES

#### THE HOUSE OF DELEGATES

The House of Delegates of the Medical Society of the State of New York will convene in the Hotel Seneca on Monday afternoon, June 2, 1930, at 2 o'clock, for the purpose of receiving and considering the annual reports of the officers and committees which were published in the Journal of May first; to transact the major items of business of the Society; and to elect officers for the coming year, beginning at

the close of the Annual Meeting on June third. Following the excellent custom of the last few years, the members of the House of Delegates will continue in session during a supper for which tickets may be purchased at \$2.50, from the office of the Secretary. The session will continue during the evening and the following morning, closing with the election of officers.

## REFERENCE COMMITTEES

The annual reports of the officers and committees of the Medical Society of the State of New York printed in the Journal of May first, are made to the House of Delegates and are considered by Reference Committees appointed by the Speaker in accordance with the Bylaws, Chapter X, Sections 10, 11 and 12, which read as follows:

Sec. 10. Immediately after the organization of the House of Delegates the Speaker shall announce such committees as he shall deem expedient for the purposes of the meeting, and the names of the members thereof. Only members of the House of Delegates are eligible for appointment on the reference committees. Such committees shall consist of five members, three members constituting a quorum, and shall serve during the meeting at which they are appointed.

Sec. 11. All recommendations, resolutions, measures and propositions presented to the House of Delegates and which have been duly seconded shall be referred immediately to the appropriate reference committee.

#### THE REPORT OF THE PRESIDENT

Charles H. Goodrich, Chairma	an. Brooklyn, Kings County
J. Lewis Amster	Bronx, Bronx
Henry J. Noerling	Valatie, Columbia
John J. Beard	Cobleskill, Schoharie
Luzerne Colville	Ithaca, Tompkins

THE REPORTS OF THE SECRETARY, THE COUNCIL, THE COUNCILLORS, AND THE BOARD OF CENSORS
Henry S. Patterson, Chairman,

Luther C. Payne. Liberty, Sullivan Edward C. Podv. Edward Morace M.

THE REPORTS OF THE TREASURER AND TRUSTEES
George M. Cady, Chairman.....Nichols, Tioga County
Morris Maslon........Glens F.
Charles C. Trembley......Saranga I.

Charles C. Trembley.....Saranae T. W. Grant Cooper.....Ogdensburg, Cornelius J. Egan......

Sec. 12. Each Reference Committee shall, as soon as possible, take up and consider such business as may have been referred to it and shall report when called upon to do so.

The consideration of the recommendations contained in the apports of the recommendations.

The consideration of the recommendations contained in the reports often requires investigations and consultations for which there are too little time or opportunity when the Reference Committees begin their labor after the opening of the House of Delegates. The Speaker has therefore announced the personnel of the Reference Committees, and the scope of their work in advance of the meeting, in order that the members may have abundant time for the consideration of the subjects referred to them, and also that every member of the State Society may have an opportunity to present his views to the proper committee.

The Committees appointed by the Speaker, Dr. John A. Card, of Poughkeepsie, contain seventy-eight members, as follows:

## THE REPORT OF THE COMMITTEE ON LEGISLATION Walter T. Dannreuther, Chairman,

Prancis M. O'Gorman Buffalo, Erie Joseph B. Hulett Middletown. Orange John J. Rainey Troy, Rensselaer Jacob A. Keller, New York City, Bronx

## THE COMMITTEE ON SCIENTIFIC WORK, AND THE COMMITTEE ON ARRANGEMENTS

Frederick J. Schnell, Chairman

No. Tonawanda, Niagara County
William B. Hanbridge......Ogdensburg, St. Lawrence
Lyman C. Lawrence
Milton G. P
Norman L.

Ralph T. Todd	Tarrytown, Westchester
Arthur S. Chittenden	Binghamton, Broome
	Long Island City, Queens

## THE ANNUAL BANQUET

The Annual Banquet of the Medical Society of the State of New York will be held on the evening of Tuesday, June third, at 7 o'clock in the Hotel Seneca. The wives of the members are invited. Tickets may be obtained at the Registration Booth.

Invitations to the banquet have been extended to Governor Franklin D. Roosevelt, Lt. Governor Herbert H. Lehman, Hon. James W. Wadsworth, and the Legislators of Monroe County and others interested in public health.

## THE ANNIVERSARY MEETING

The Charter of the Medical Society of the State of New York requires the Society to hold an annual or Anniversary meeting, but does not specify when, where or how to hold it. The officers of the Society have therefore arranged that the one hundred and twenty-fourth Annual Meeting will be held in the dinner hall immediately after the Annual Banquet. An address of welcome will be given by

Dr. Walter A. Calihan, Chairman of the Committee on Arrangements.

Dr. James N. Vander Veer of Albany will deliver his exaugural address as the retiring President of the Medical Society of the State of New York.

Dr. William H. Ross, of Brentwood, will deliver an inaugural address as the incoming President of the State Society.

#### THE ENTERTAINMENT

The Committee on Arrangements of the Medical Society of the State of New York has prepared an excellent entertainment after the satisfactory precedent set by the Committee on Arrangements last year when the Players' Club of Utica, staged an opera written with a medical flavor. This year's entertainment will consist of a minstrel show in which the performers will be members of the Medical Society of the County of Monroe. The numbers on the program have been specially composed and arranged for a medical audience, and the characteristics and individualities of many well-known officers and members of the State Society will be recorded and immortalized in verse and song and dance.

#### EXHIBITORS' DINNER-SMOKER

The financial prosperity of the Medical Society of the State of New York depends largely on the advertisers in the Journal and Directory, and the exhibitors in the Technical Exhibit. Appreciating the good will of the advertisers and exhibitors, the Society will give a dinner-smoker to the exhibitors on the evening of Monday, June second, under the direction of Mr. Joseph B. Tufts, advertising manager. Brief addresses will be made by officers of the State Society, but the principal object of the dinner-smoker is to promote a spirit of sociability and good fellowship on which business depends quite as much as on financial considerations. Good will is powerful in advertising as it is in medicine.

## EXTRA-CURRICULAR ARRANGEMENTS

The annual meeting of the Medical Society of the State of New York will have many attractive features in addition to those set forth in the formal announcements outlined in this issue and in those of April fifteenth and May first. There is a sociability to be found in the hotels and the meeting rooms. Physicians will have no difficulty in finding suitable hotels, a list and rates of which appear on page 607. They will also find congenial friends in abundance, and will form new ones aplenty. The members may bring their wives, confi-

dent that they will find recreation and entertainment. A Ladies' Entertainment Committee, under the leadership of Mrs. Austin G. Morris of Rochester, will provide a luncheon and automobile drive on Tuesday, June third, and will have representatives on hand at the Registration Booth to advise and assist the ladies in regard to shops, theatres, and side trips.

Rochester, the third largest city in New York State, is noted for its points of interest. There is the Genesee River whose falls and water power determined the site of the city in

the early thirties of the last century. There is the gorge and park below the falls and extending to Charlotte, the port of Rochester on Lake Ontario, now a part of the City. There is also the broad valley of the River extending back through rolling farm lands, and through the beautiful Letchworth Park and gorge at Mount Morris. There are also beautiful parks and drives within the city including that around the Municipal Water Works. All these features are within easy riding distance by automobile or taxi.

Everybody knows the Eastman Kodak Company and the benefactions which have made Eastman, Rochester's leading citizen. Those with leisure will enjoy the concerts held in the beautiful music hall constructed by Mr. Eastman.

The local Committee on Arrangements, under the chairmanship of Dr. Walter A. Calihan, and the Medical Society of the County of Monroe, of which Dr. Calihan is also President, have perfected the arrangements which will insure comfort and satisfaction to every physician and lady who comes to the meeting.

#### WOMEN'S MEDICAL SOCIETY

The women physicians of New York State are loyal members of the Medical Society of the State of New York; and in addition they maintain their own organization which meets during the week of the State Society, but at hours which conflict as little as possible with the State Society sessions or its other activities which are announced on the program.

The annual meeting of the Women's Medi-cal Society of the State of New York will therefore be held at 9:30 A.M. on June 2, 1930, in the Hotel Seneca, Rochester, N. Y. The scientific program will begin at 2:15 P.M. A banquet will be held at 6:30 P.M. and

will be followed by a historical pageant.

Marion S. Moore, Secretary.

## PUBLIC MEETING ON PERIODIC HEALTH EXAMINATIONS

A public dinner and meeting has been arranged by the Committee on Periodic Health Examinations of the Medical Society of the State of New York with the cooperation of the Medical Society of the County of Monroe and the Rochester Chamber of Commerce to be held on June 4, 1930, at 6:30 P.M. in the Chamber of Commerce rooms at 55 St. Paul Street, Rochester, N. Y. Tickets are two dollars each and dress will be informal. The Committee extends an invitation to the physicians and their friends who are attending the Annual Meeting of the Medical Society of the State of New York. Information may be obtained at the registration booth of the New York State Society.

The program is on the topic, "A Health Examination for Every Citizen of the State." The speakers are as follows:

- 1. Introduction-William A. Sawyer, M. D., Medical Director. Eastman Kodak Company.
- 2. Address of Welcome-Isaac Adler, Acting Mayor, City of Rochester.
- 3. Response—James N. Vander Veer, M. D., Retiring President.
- 4. The Present Situation—C. Ward Crampton, M. D., Chairman Committee on Periodic Health Examinations, Medical Society of the State of New York.
- 5. Old Programs and New-Thomas Parran, Jr., M. D., Commissioner of Health, State of New York.
- 6. The Woman's Dynamic Program—Harriet W. Mayer, New York State Federation of Women's Clubs, State Chairman, Committee on Public Health.
- 7. The Medicine of the Future—George W. Crile, M. D., The Cleveland Clinic and The Gorgas Memorial Institute. Introduced by Charles Gordon Heyd, M. D.
- 8. Looking Forward for the Committee on Public Relations-James E. Sadlier, M. D., Chairman.
- 9. For the Committee on Public Health and Medical Education—Thomas P. Farmer, M. D., Chairman.

For the Medical Society of the State-William H. Ross, M. D., President.

## NEW YORK STATE ASSOCIATION OF PUBLIC HEALTH LABORATORIES

The New York State Association of Public Health Laboratories, of which Dr. Leo F. Schiff, director of the Clinton County Laboratory, Plattsburg, is president, will hold its fourteenth annual meeting in Rochester at the School of Medicine and Dentistry, University of Rochester, on June 2 at 2:00 p.m. (standard time). The other officers of the Association are: Dr. George M. Mackenzie, Otsego County Laboratories, Cooperstown, vice-president; Mary B. Kirkbride, State Laboratory, Albany, secretary-treasurer. Dr. Stanhope Bayne-Iones, Health Bureau Laboratories, Rochester, and, Dr. James A. Dickson, Montgomery County Laboratory, Amsterdam, are members of the Council.

The scientific program of the Association will be as follows:

Comparison of the Dominick-Lauter presumptive test for B. coli in water with that of "Standard Methods." Harold W. Leahy, Health Bureau Laboratories, Rochester.

Streptococci of the udder in their relation to a septic sore throat epidemic. Robert S. Breed and (by invitation) G. J. Hucker, Geneva City Laboratory, Geneva.

A case of systemic blastomycosis. Istvan Gaspar, Rochester General Hospital Laboratory, Rochester.

A strain of B. Morgani I isolated from a

parrot. Marion B. Coleman, State Laboratory, Albany.

Serological tests for syphilis in feebleminded. Alexander N. Bronfenbrenner, Letchworth Village Laboratory Thiells.

A study of the Wassermann reaction in pregnancy. Frederick A. Hemsath, Lying-In Hospital Laboratory, New York City.

Undulant fever. Final report on joint investigation by members of the Association. Stanhope Bayne-Jones, Health Bureau Laboratories, Rochester.

Address. Thomas Parran, Jr., Commissioner, New York State Department of Health.

As part of the scientific program there will be various exhibits and demonstrations, including a demonstration, of protozoology and helminthology, apparatus for making motion pictures of bacteria, materials and set-up for blood grouping tests, microscopic examination of milk (lantern slides), and museum specimens from the Department of Pathology of the School of Medicine.

The conference of managers and directors of approved laboratories of New York State, with Dr. Cornelius F. McCarthy, Auburn, chairman, will be held at the Hotel Seneca on Monday morning, June 2, to discuss general and administrative laboratory problems.

#### CLINIC DAY

The Medical Society of the County of Monroe is arranging a clinic day, Thursday, June 5th, following the official closing of the State Convention, to which all the members of the Medical Society of the State of New York and guests are invited. The detailed program will be ready for distribution with the general program of the Convention. The general plan of the clinics will be such as to interest all who plan to remain for them. The various hospitals of Rochester will present clinics on interesting subjects from 8:30 A.M. to 10:30 A.M. The

University of Rochester, School of Medicine and Dentistry, has prepared an interesting schedule of papers to be presented by the Staff of the Medical School, beginning at 11:00 A.M. The Medical School has invited all the members and guests of the State Society for luncheon on that day.

The following hospitals will also present clinics: Highland Hospital, Rochester General Hospital, Park Avenue Hospital, St. Mary's Hospital, Genesce Hospital, Iola Sanatorium, and Rochester State Hospital.

#### COMMITTEE ON PUBLIC RELATIONS

The regular monthly meeting of the Committee on Public Relations was held on Thursday, April 17, in the Hotel Pennsylvania, with the Chairman, Dr. James E. Sadlier of Poughkeepsie, presiding, and all the members present.

Dr. W. H. Ross, the Secretary, reported that some physicians had questioned the economic policy of giving free service to clinics organized for the prevention of any disease, such as diphtheria. On the other hand, physicians who had adopted preventive work in their private practice had profited financially, as also any doctor could who took advantage of the publicity given by clinics and popular health articles in newspapers and magazines.

Dr. Sadlier reported that the Medical Society of Steuben County had done an excellent piece of original work in arranging for a joint meeting on April 29, with representatives of all the

local organizations engaged in public health work.

Dr. Sadlier also reported on the progress of the county medical surveys, and the increasing interest taken in them by the officers of the counties.

The principal item of business was a report by Dr. O. H. W. Mitchell on Student Medical Service in the twenty-eight colleges and universities of New York State. Dr. Mitchell summarized the replies to an extensive questionnaire which he had sent to all the institutions and showed that the service varied widely from almost nothing to that equalling the medical service of the United States Army.

Dr. Mitchell will prepare his report in a form suitable for publication in the Journal.

W. H. Ross, Secretary.

## COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

The meeting of the Committee on Public Health and Medical Education was held on Thursday, April seventeenth, at 10:30 a.m., at the Hotel Pennsylvania, New York City. All members of the committee were present except Doctor Polak who was excused on account of illness.

Dr. George W. Kosmak discussed the relation of the medical profession to lay organizations engaged in the promotion of cancer elimination. He said that the American Society for the Control of Cancer was a lay organization dealing with what is largely a medical matter. It is now in process of reorganization, and physicians should have definite knowledge of the Society's plans before taking action in regard to its policy. Dr. Kosmak also spoke of the danger of phobias arising from sensational lectures of a popular nature.

Dr. Stanton described the efforts made by the State Committee for the Control of Cancer to raise an endowment in Schenectady County, which he had opposed.

The following resolutions was moved by Dr. Chandler and seconded by Dr. Bayne-Jones and carried:—

Resolved, that since the cause of cancer is not definitely known and its treatment not definitely settled, the Committee on Public Health and Medical Education feels that information to the public about cancer should be in the hands of medical men whose minds are receptive to any suggestion, treatment, thought or plan of action concerning this disease which will stand scientific investigation, and that this committee support all efforts toward such scientific investigation.

There then followed a general discussion regarding educational work with physicians on the subject of cancer. The following resolution was moved by Dr. Groat, seconded by Dr. Chandler, and carried:

Resolved, that the Committee on Public Health and Medical Education incorporate among its postgraduate courses lectures on cancer.

The following resolution was moved by Dr. Chandler, seconded by Dr. Stanton, and carried:

Resolved, that it is the opinion of this committee that the work of Dr. Swan, as director of the New York State Committee of the American Society for the Control of Cancer has been a benefit to the people of the State. The Committee recommends that the future direction of this work be in the hands of a regular licensed physician who is a member of the Medical Society of the State of New York.

Dr. W. I. Dean of Rochester appeared as a representative of the Up-State Committee of the American Society for the Control of Cancer and told of the aims and accomplishments of that committee.

The Committee then took up for discussion the subject of the plan for publication in the Journal of the State Society of short articles on "How Physicians Can Practice Preventive Medicine in Their Regular Routine Work." Dr. Stanton said that he thought that three-fourths of the physicians' work is in preventive medicine, and that the physician already was doing a great deal of this work.

Dr. Groat felt that while at the present time a large part of the physician's work was in preventive medicine, it would be very well to crystallize ideas regarding preventive medicine in short articles such as were contemplated by the plan under discussion.

Dr. Chandler felt there was great need to publish articles which would acquaint the physician with the activities of this committee and especially the accomplishments up to the present time. Dr. Longstreet also emphasized this point.

Dr. Greene approved publishing in pamphlet form all the articles together after they had appeared in the State Journal.

It was mutually agreed that the plan should consist of one short article dealing with one subject in the practice of medicine to be published in each issue of the Journal. The article would be prepared from the standpoint of a physician dealing with a patient having some complaint rather than one from the viewpoint of a person coming to the physician for a periodic health examination, and would stress the important things from a preventive standpoint which the physician should look for; also apparently minor conditions which should receive treatment in order to obviate future illness; and finally instructions as to advice to give to the patient. While the article would not be a guide in the manner of making a periodic health examination, still it would prove helpful to the physician so engaged, and would interest the physician in such examination and undoubtedly educate the patient also to the benefit of such examinations. It was agreed that the subjects as originally outlined by the chairman should form a list to begin work upon and that all articles should be concise and short. It was also agreed that the Publication Committee should be requested, if the plan were put into effect, to publish the articles in sequence, that the articles as near as possible appear on the same page in each issue, and that the article be published without revision after it had left the committee's hands.

It was also agreed that one member of the committee be asked to review each article, not so much from the standpoint of the material which it contained, but whether or not it fulfilled the purpose of the plan. It was also agreed that it would be best to omit the author's name and publish the articles over the name of this committee. The chairman was authorized to appoint a sub-committee to consider the details of this plan. The committee decided that it would seem best to obtain all the articles before beginning the publishing of any of them.

Doctor Lawrence addressed the committee and called its attention to the large number of health officers who at the present time are not members

of the State Medical Society.

At luncheon the committee joined the Committee on Public Relations, and under the chairmanship of Dr. Vander Veer, took up the question of the subject of cancer. Dr. R. V. Brokaw,

Executive Secretary of the American Society for the Control of Cancer spoke of the work of his Society mentioning the establishment of cancer clinics, and of fellowships for the study of cancer, and said that it was the policy of his organization to use existing agencies as far as possible to carry out its work.

Dr. Dean reviewed the organization of the State Committee under Dr. Swan and the work which had been done by this Committee. He also discussed the financial matters of the committee and how it had raised funds. Dr. Dean emphasized the point that the State Committee under Dr. Swan had tried to carry out their work primarily through the medical profession.

THOMAS P. FARMER, M.D., Chairman.

### DEFENSE IN CONTRACT CASES

The Executive Committee of the Medical Society of the State of New York has recently been in receipt of a number of inquiries regarding the coverage afforded by our group plan in the so-called "contract" cases. It appears that these inquiries may represent a desire on the part of the members of the Society generally, to be informed on this subject. Therefore, the Executive Committee has requested the Committee on Group Insurance, through the medium of the State Journal, to write this article setting forth the provisions of the group policy pertinent to the subject-matter of this article.

In cases where the complaint alleges that the defendant-physician made a definite contract, either orally or in writing, with his patient to cure or to secure a certain definite result or has made a guarantee with respect to his operation or treatment, and it is further alleged in the complaint that the defendant has breached the said contract with resultant damage to the patient, the physician in such case is not entitled to indemnity under our group plan. No contract of this kind should be made by any physician, as it is impossible for any physician to guarantee the result of his work.

Our group policy provides defense and indemnity only "on account of any malpractice, error or nistake committed or alleged to have been committed" during the policy period. This insurance is not written and could not be written to cover breaches of contract, and to emphasize this, each physician, when he applies for insurance, must declare among other things: "I have

not in force and I will not enter into any special contract or agreement, oral or written, guaranteeing the result of any operation or treatment." It sometimes happens that where a doctor is sued for a breach of contract on an alleged contract to cure, he denies having made such contract. In such a case, if we are convinced of the truthfulness of the doctors denial, our general counsel defends him but the physician is advised that should a judgment be recovered upon the breach of contract, that is to say, should the court and jury find that the plaintiff's claim that the doctor did in fact make a contract to cure is true, then the physician will not be indemnified against such a judgment.

We deem it pertinent in this connection to point out that our group policy does afford full indennity where the complaint in an action against a physician charges that the defendant entered into a contract to exercise a reasonable degree of care and skill in treating his patient, and that he failed to use reasonable care and skill and, therefore, breached his contract with his patient. This type of allegation contains nothing but a reiteration of the implied contractual obligation which by law flows from the relation of patient and physician. One of our appellate courts has already denominated an action where the complaint contained substantially these allegations as one, not of contract, but of malpractice.

JOHN A. CARD, Chairman CHAS. G. HEYD, Group Insurance Committee.

#### PUBLIC RELATIONS SURVEY No. 13-SCHENECTADY COUNTY

1. In the county there are about 132 doctors of whom 125 dwell in the City of Schenectady, and 125 belong to the County Medical Society.

Hospitals:

Ellis Hospital—General

Glenridge Sanitarium — Tuberculosis Hos-

pital

Isolation Hospital—City Isolation Hospital

Free clinics at the Ellis Hospital to care for County and City cases:—

Eye, Ear, Nose & Throat

Medical and Surgical

Neurology

**Pediatrics** 

Obstetrics

Skin

Free Clinics at the City Health Centre to care for city cases.

Eye, Ear, Nose & Throat Clinic

Medical and Surgical

**Tuberculosis** 

Child Welfare

Pre-Natal

Congenital

Venereal

Cardiac

Dental.

Mental Hygiene

- 2. The County Medical Society has no plans for the future, except work being done in the city proper.
- 3. The Tuberculosis Committee uses stamp money to maintain a Children's Health Camp for Summer. The Camp provides for forty undernourished children at a six weeks' camp. It gave funds for publicity for Tuberculosis campaign, and toxin antitoxin campaign. It cooperates with the Health Department and the Medical Society in every way. It has no nursing service.

4. The Parent-Teacher's organization is well organized. At present it is interested in prenatal work, and has home nursing courses conducted by the Red Cross.

The Red Cross through Public Health Nursing Association conducts clinics in various towns in the county on various child health phases. It supplies bedside nursing at a small cost per hour.

5. The Rotary Club is interested in a camp for boys.

The Kiwanis is interested in crippled children. The Lions Club furnished glasses for poor people, and is interested in handicapped children.

The Junior League does Family welfare work. The Business and Professional Women's Club sponsors crippled girls.

6. There are twenty-nine public schools in the city, with 7 school physicians and 17 school nurses who act as health teachers, 1 orthopedic worker, 1 school dentist, 2 dental hygienists, and 1 oculist.

There are 45 schools in the county, exclusive of the city schools. Among the larger ones, 15 have formed a unit which hires a school physician and a school nurse. Any physical defects are noted and recommended to a family physician and also checked up and followed by the school nurse during the school year. The children in this unit get the same medical attention as do the children in the city. The 30 county schools outside this unit receive no medical attention.

- 7. Each town has a Health Officer. All cooperate, and are inclined to be progressive and willing to undertake any health program which will be backed up by the public.
- 8. The peculiar health needs of the county are more funds to have a larger personnel to carry out worthwhile health measures in a more progressive manner.

J. H. Collins, M.D.

Commissioner of Health.

Schenectady, N. Y.

April 29, 1930.

#### OBSTETRICAL SYLLABUS

A Syllabus of Lectures on Obstetrics for Nurses has been prepared by a Committee appointed by the American Gynecological Society, and is now ready for distribution to those interested in the subject of nurse training. Copies

may be obtained from the Chairman of the Committee, at the nominal price of fifty cents, by addressing a request to 23 East 93rd Street, New York City.

George W. Kosmak, M.D.

#### CONFERENCE ON PUBLIC HEALTH EDUCATION

A conference on Public Health Education was held in Albany on April twenty-fourth, in the Executive Chambers, at the call of Governor Franklin D. Roosevelt.

Plans for a health conference arose out of the desire of Federated Women's Educational organizations of New York State to concentrate upon a subject of common interest in the educational program of their local groups. Health was chosen as the topic of the year. The secretary of the Federation was authorized to confer with official and non-official professional organizations to secure their cooperation as a source of program and instruction. Professional, official and non-official organizations which joined in the conference were represented as follows:

New York State Department of Health.

New York State Department of Education.

New York State Department of Agriculture and Markets.

New York State Colleges at Cornell University. New York State Medical Society.

State Charities Aid.

American Child Health Association.

New York State Federation of Women's Clubs.

Woman's Christian Temperance Union of the State of New York.

tate of New York. New York State Federation of Home Bureaus.

New York League of Women Voters.

New York State Congress of Mothers and Parent-Teacher Associations.

Home Economics Committee, New York State Grange.

Home Economics Association of New York State.

The Consumers League of New York State.

The general need for an educational health program was recognized, and the principal point that was considered was the scope of the plan and the machinery for carrying it out. The conference discussed the radio, printed periodicals and lectures. It was decided that since the State Department of Health has been engaged in these forms of health publicity and education for fifteen years, its office should continue to be the center for preparation and distribution of the educational material.

Two members of the State Extension Service in the State College of Home Economics, are spending full time until July 1st in the effort to make available to the organization groups a knowledge of the working plans of official health organizations.

To this end, it is suggested that each official head of an official organization name a person on his staff with whom these persons may confer from time to time.

The Medical Society of the State of New York has frequently discussed the advisability of conducting an educational health program, but has hitherto left the execution of the plans to the Department of Health of the State and its larger cities. The Federation of Women's Educational organizations may provide the means and the inspiration for carrying on the educational program which the physicians of New York State will approve.

#### HISTORICAL EXHIBIT

To the Members of the Medical Society of the State of New York:

Your President has been approached by the director of the State Museum in the State Education Building at Albany, New York, who has outlined a plan he has in mind for the collection and permanent exhibition of old books, old instruments and paraphernalia of all sorts relative to the practice of medicine in this State.

This he is also doing with the other professions of the State; and in view of the new and proposed State Museum Building, it would seem that our participation in an exhibition of this sort would be very appropriate.

I am therefore making the suggestion to the individual members of the Medical Society in

this State that they comb their garrets and other places where these ancient and historical things might be located and send them, either to me, or to the State Museum, State Education Department, Dr. Charles Adams, Director.

It would be the more interesting and instructive if each article was labelled with a short statement as to what the instrument was used for, the owner's name with his address, the approximate date of its use, and the approximate age of the same. In that way I believe we could save many of the old historical things that are rapidly being thrown into the discard and which will be of great value from an exhibition standpoint in years to come.

JAMES N. VANDER VEER, M.D.

#### COMMISSION TO REVISE HEALTH LAWS

The newspapers of May first carried an announcement by Governor Franklin D. Roosevelt that he had appointed a Special Health Commission for the purpose of investigating the laws of New York State relating to health, and to suggest new legislation in order that New York State may take advantage of the progress in general medicine and public health that has occurred during the seventeen years that have elapsed since a similar commission proposed the present public health law. The Governor's letter to each member of the Commission is as follows:

"Among the State Departments with which I have had to familiarize myself as Governor, none is of more vital importance to the people of the State than that of public health. New York is in an enviable position among the forty-eight states in the standing of its health work. The frame work of the State and local health departments, and their relation one to the other, are based in their essential features on a comprehensive revision of the public health law and program of activities formulated in 1913. The law of 1913 was enacted upon the recommendation of a Special Public Health Commission of citizens appointed by the Governor, of which the late Doctor Hermann M. Biggs was chairman. The recommendations of that Commission resulted in extensive reorganization and in marked development of public health activities, and under the leadership of Doctor Biggs himself, as Commissioner, from 1913 to 1923, and of his deputy and successor, Doctor Matthias Nicoll, Jr., from 1923 to 1930.

"It has occurred to me that developments in the science and administration of public health in the past seventeen years make desirable at this time a reconsideration by a similar commission of present and future public health needs of the State.

"I am therefore appointing a Special Public Health Commission, and am asking it to take into consideration the public health activities of State and local authorities, and their relations one to

the other, as well as recent progress in public health in other states and abroad. I am asking the Commission to submit to me any conclusions and recommendations which it may deem wise relating either to the legislative or administrative aspects of public health.

"I take pleasure in inviting you to serve as a member of this Commission, and enclose a list of those who are being asked to serve. I hope you will find it possible to render this important serv-

ice to the people of the State."

The committee appointed by the Governor is as follows:

Dr. Livingston Farrand, Chairman, President of Cornell University, Ithaca.

Dr. George W. Cottis, Jamestown.

Dr. Simon Flexner, Director Rockefeller Institute for Medical Research, New York City.

Mr. Homer Folks, Secretary, State Charities Aid Association, Yonkers.

Dr. Edward L. Keyes, President American Social Hygiene Association, New York City.

Mr. John A. Kingsbury, Secretary, Milbank Memorial Fund, New York City.

Mrs. Henry Goddard Leach, President of the League of Women Voters, New York City. Hon. Henry Morgenthau, New York City.

Dr. Matthias Nicoll, Jr., County Health Commissioner of Westchester County, Former State Commissioner of Health.

Mr. John M. O'Hanlon, Secretary, New York State Federation of Labor, Troy.

Dr. Thomas Parran, Jr., State Commissioner of Health, Albany.

Dr. William H. Ross, President-elect, Medical Society of the State of New York, Brentwood.

Hon. Gerard Swope, President, General Elec-

tric Company, Schenectady.

Miss Katherine Tucker, Director National Organization for Public Health Nursing, New York City.

Dr. Linsly R. Williams, Director, New York Academy of Medicine, New York City.

#### LEGISLATION, FINAL BULLETIN

The Governor has disposed of the last of the bills that were left with him by the legislature and we can, therefore, send out our final bulletin, although we might have probably done so earlier, because there were very few bills left with the Governor in which we had a particular interest.

A word might be said as to the fate of the few bills in which we were very particulary interested. The two Esmond chiropractic bills never came out of Rules Committee. The Porter-Brown chiropractic bill was reported in the Assembly and failed of passage by a vote of 47 to 77. A few days later the bill was brought from the table and voted upon again; the vote this time stood 67 to 70. The shift in vote was not entirely due to an increased desire on the part of the legislatures to enact a chiropractic measure, but a portion of it was complimentary to the introducer.

It would be well to urge every County Society committee to unite with the local Committee on Public Relations for the purpose of developing interest among the lay folk against chiropractic.

The legislators are endeavoring to do the right thing, but they have had many more requests from lay people for recognition of the chiropractors than they have had petitions opposing the measure from lay folk. We cannot lose patience with the legislator when he says that opposition on the part of the lay people is more to be considered than opposition from the medical profession, because our opposition cannot help but be considered, to a certain degree at least, as selfishness. We cannot agree with the legislator in this diagnosis, but we must admit that he has some justification for taking such a position. However, if the two committees of your County Society interest ten or more influential lay folk to the point where they will write their legislators during the summer that they do object to any lowering of the educational standards set by the Board of Regents for those who would practice the healing art, regardless of the name under which they wish to be licensed, we are convinced you will be doing a good piece of work and will help us greatly in our efforts with the Legislature next year.

The optometry bills were both lost in the Assembly. The one that would authorize boards of trustees to employ optometrists for the examination of school children's eyes, remained on the table without an effort being made to lift it. The "Doctor Optometry" bill was lost by a vote

of 61 to 55.

The osteopathic bill was lost in the Assembly without a slow roll call. Although the osteopaths were exceedingy active and thousands of letters from patients came to the legislature asking reconsideration of the bill, no attempt was made to bring it out a second time.

The hospital licensure bill failed because we amended it too late in session. The amendment was on our own suggestion and we believe was very worth while. This bill will be worked over during the summer and will be in satisfactory shape by the time the 1931 Legislature convenes.

The bill authorizing the creation of a medical advisory council in the Department of Labor passed the Assembly, and reached the point of being reported for final vote in the Senate, when it was opposed by Commissioner Perkins. She has expressed herself as not opposing the general plan of having an advisory medical council, but she thought that this bill was much too far reaching, and she has offered to assist in rewriting it for next year.

The bill authorizing free choice of physician by an injured workman, was never reported out by the Committee on Labor and Industries. If this bill is to succeed, it seems essential that Federated Labor make a more definite effort to support it than was made this year.

There follows a list of the bills which the Governor signed from among those reported in our bulletins during the session. The other bills were either killed in committee or on the floor or vetoed by the Governor. There were many of them, and if any one is particularly interested in knowing more about some of them, we shall be glad to give him what information we can.

Senate Int. No. 17—Fearon, permits a child welfare board to grant allowance to a mother, permanently incapacitated and confined in an in-

stitution or is insane.

Senate Int. No. 20—A. J. Kennedy (Assembly Int. No. 188—Messer), extends to veterans of any war provision now limited to World War veterans for \$500.00 annuity for those permanently and totally disabled by reason of loss of sight.

Senate Int. No. 325—Fearon, provides for return with mother of a child born outside correctional institution, if mother is physically fit to care for child, which shall not remain in institution after it is one year old; and relative to women held as material witnesses.

Senate Int. No. 532—Fearon (Assembly Int. No. 772—Shonk), permits a town board to appoint an assistant town public welfare officer

and other necessary employees.

Senate Int. No. 643—Kirkland (Assembly Int. No. 846—F. M. Smith), provides section for licensing of dogs shall not apply to dogs confined for purpose of research, to premises of educational or research institutions.

Senate Int. No. 849—Mastick (Assembly Int. No. 1088—Bernhardt), provides security against

old age want.

Senate Int. No. 1615—Fearon, increases number of trustees of New York Academy of Medicine.

Senate Int. No. 1725—Pitcher (Assembly Int. No. 2110—Lattin), provides for milk control and inspection by state health commissioner, and appropriates \$90,000.00.

Assembly Int. No. 212—Bernhardt (Senate Int. No. 930—Hickey), provides for adequate medical and nursing care of a woman confined in a public home and about to give birth to a child.

Assembly Int. No. 400—Rice (Senate Int. No. 256—Webb), provides applicant for admission to examination for medical license must have completed not less than 4 satisfactory courses of at least 8 months each in a medical school, instead of studying not less than 4 school years, etc.

Assembly Int. No. 424—Cornaire (Senate Int. No. 341—Gates), adds to occupational diseases for which compensation may be had, radium poisoning or disability, disability from blisters or abrasions, from bursitis or synovitis and for dermatitis or venenata.

Assembly Int. No. 465—Lattin (Senate Int. No. 398—Pitcher), authorizes local health boards to impose penalties for violation or failure to comply with regulations of state sanitary code.

#### COMMISSION TO REVISE HEALTH LAWS

The newspapers of May first carried an announcement by Governor Franklin D. Roosevelt that he had appointed a Special Health Commission for the purpose of investigating the laws of New York State relating to health, and to suggest new legislation in order that New York State may take advantage of the progress in general medicine and public health that has occurred during the seventeen years that have elapsed since a similar commission proposed the present public health law. The Governor's letter to each member of the Commission is as follows:

"Among the State Departments with which I have had to familiarize myself as Governor, none is of more vital importance to the people of the State than that of public health. New York is in an enviable position among the forty-eight states in the standing of its health work. The frame work of the State and local health departments, and their relation one to the other, are based in their essential features on a comprehensive revision of the public health law and program of activities formulated in 1913. The law of 1913 was enacted upon the recommendation of a Special Public Health Commission of citizens appointed by the Governor, of which the late Doctor Hermann M. Biggs was chairman. The recommendations of that Commission resulted in extensive reorganization and in marked development of public health activities, and under the leadership of Doctor Biggs himself, as Commissioner, from 1913 to 1923, and of his deputy and successor, Doctor Matthias Nicoll, Jr., from 1923 to 1930.

"It has occurred to me that developments in the science and administration of public health in the past seventeen years make desirable at this time a reconsideration by a similar commission of present and future public health needs of the State.

"I am therefore appointing a Special Public Health Commission, and am asking it to take into consideration the public health activities of State and local authorities, and their relations one to

the other, as well as recent progress in public health in other states and abroad. I am asking the Commission to submit to me any conclusions and recommendations which it may deem wise relating either to the legislative or administrative aspects of public health.

"I take pleasure in inviting you to serve as a member of this Commission, and enclose a list of those who are being asked to serve. I hope you will find it possible to render this important serv-

ice to the people of the State."

The committee appointed by the Governor is as follows:

Dr. Livingston Farrand, Chairman, President of Cornell University, Ithaca.

Dr. George W. Cottis, Jamestown.

Dr. Simon Flexner, Director Rockefeller Institute for Medical Research, New York City.

Mr. Homer Folks, Secretary, State Charities Aid Association, Yonkers.

Dr. Edward L. Keyes, President American Social Hygiene Association, New York City.

Mr. John A. Kingsbury, Secretary, Milbank Memorial Fund, New York City.

Mrs. Henry Goddard Leach, President of the League of Women Voters, New York City.

Hon. Henry Morgenthau, New York City. Dr. Matthias Nicoll, Jr., County Health Commissioner of Westchester County, Former State Commissioner of Health.

Mr. John M. O'Hanlon, Secretary, New York

State Federation of Labor, Troy.

Dr. Thomas Parran, Jr., State Commissioner of Health, Albany.

Dr. William H. Ross, President-elect, Medical Society of the State of New York, Brentwood.

Hon. Gerard Swope, President, General Electric Company, Schenectady.

Miss Katherine Tucker, Director National Organization for Public Health Nursing, New York City.

Dr. Linsly R. Williams, Director, New York Academy of Medicine, New York City.

### THE DAILY PRESS

#### PROHIBITION PSYCHOLOGY

A pictorial statement by J N Ding in the New York Herald Tribune of May 1 and May 2, 1930

Prohibition is not a favorite topic of conversation among doctors, probably because they do not know any more about the subject than other people do. They may learn a lot from J. N. Ding,

who discusses the subject clearly with a minimum of words and a maximum of action.

#### ANT JAW SUTURES

The clips used for holding together the edges of wounds has its analogue in the jaws of giant ants. The New York Herald Tribune of April 16 has the following report of the use of ants for stitching wounds:

"The use of 'surgical ants' with powerful jaws to stitch the wounds of human beings and other primitive medical practices developed by the Indians living far in the interior of Peru are described ir a report received today from the Field Museum of Natural History from the Marshall Field botanical expedition to the Amazon.

"'The natives of the equatorial forest show

great originality and dexterity in the treatment of wounds and illness, 'writes Llewelyn Williams, leader of the expedition's Peruvian section. 'In the case of wound, a certain ant which has very powerful jaws is sought, and the ant is made to bite the severed edges of the skin and thus bring them into juxtaposition. In the operation the ant surgeon loses its own life, for after it has drawn the closed skin with its jaws, its body is snipped off, and the lifeless head remains with its death off, and the lifeless head remains with its death grip on the skin until the wound is healed. Sometimes these Indians are found with half a dozen of these ants' heads holding a large wound closed.'

#### LIABILITY FOR A GUEST

Rural coctors are especially liable to imposition by self-invited riders. If the guest is injured, the doctor may be held liable for damages. But California has changed that law, as shown by the following editorial in the New York Times of

April 10:

"Even though a California court has decided that the State law exempting "guest" passengers in automobiles from the right to claim damages from drivers in the event of injury may not be applied retroactively, the fact that the law protects such drivers in the future will come as a relief to itinerant motorists. What California has done other States may duplicate.

"The problem of the 'hitch-hiker' is one which

motorists everywhere have to face. There are at least two dangers in giving a lift to strangers: the danger of being attacked, and—except now in California—of being sued in case of accident. The number of would-be hitch-hikers is legion. Nowhere are there so many as in California. Incidentally, only a venturesome motorist would give a lift to some of the ferocious looking creatures to be seen on the California highways.

"The safest rule is, of course, not to take on 'guest' passengers. If the danger of being sued is removed, the next question is whether the would-be guest seems to be one who believes in reversing the biblical injunction to requite evil

with good."

#### THE SURVIVAL OF THE FITTEST

James J. Montague, writing verse for the department of "More Truth Than Poetry" in the

No wonder that the cave man
Is vanished now and dead;
He must have been a brave man
To lead the life he led.
I never could have carried on
And kept myself from need
If I had had a mastodon
To feed.

The cave man's nearest neighbors
Consisted of a brood
Of tigers toothed with sabers
And fond of human food.
He naturally kept all day
Within his cavern lodge,
With such a greedy beast of prey
To dodge.

New York Herald Tribune of April 17, expresses a Darwinian truth in the following poem:

His ways were shy and furtive,
His gait was sly and slow,
He was not self-assertive
Or braggadocio;
And when his nightly task was o'er
And home his way he'd wend,
He had a hungry dinosaur
to tend.

The trials he labored under
Wore out his nerve and grit;
It isn't any wonder
That he was thick of wit.
With predatory beasts about
His chance of life was small;
I marvel that he stuck it out
At all.

#### MILLENNIAL PHANTASIES

Doctors are just about like other professional men, as is revealed in the following lines by W. J.

#### THE DOCTOR

The doctors never, never try To mystify nor magnify A symptom, and they only will With diffidence present a bill.

#### THE LAWYER

It is uncivil to indict
A lawyer as a parasite:
A lawyer loves simplicity
And hesitates to take a fee.

Funk from The Lantern column of the New York Herald Tribune of April 24.

#### THE BROKER

A broker never fails to tell A customer when he should sell, And when he says to buy, why then The prices pop right up again.

#### THE ARCHITECT

An architect will estimate A budget that is accurate, Meticulously, floor by floor— It never costs a penny more.

# BOOK REVIEWS

PRINCIPLES AND PRACTICE OF DERMATOLOGY. By NOXON TOOMEY, M.D. Volume Three. The Treatment of Skin Diseases in Detail. Octavo of 512 pages. St. Louis, The Lister Medical Press, 1930. Cloth, \$7.50.

The author in this volume of some 500 pages has arranged the subject, as far as possible, according to etiological classification. In most instances there is a brief statement as to causation, following which treatment is given in detail.

The first impression one gains on opening with the first disease taken up, which happens to be eczema, is the stilted style of the author. The words chosen are not those in common use in dermatological literature. Fortunately this becomes less marked in the body of the work. It is impossible in a review of a work dealing with so many different diseases as we find in dermatology, to do more than touch on the chief or more important conditions. In the section on Rosacea, his prognosis seems to the reviewer to be too unfavorable. He also does not mention the value of Hydrochloric Acid in this condition nor does he mention the frequent hypoacidity which patients suffering with it show,

Under Raynaud's Disease he mentions Lead as a possible cause but in his discussion of Scleroderma he makes no mention of the possible association of this condition

to a heavy metal retention.

In the treatment of Adenoma Sebaceum no mention is made of the beneficial effect of ultraviolet light applied under pressure, but this is recommended in some types of Lupus Erythematosus, a condition in which any form of light application is attended with a possibility of dis-semination of the eruption. However in Lupus Erythe-matosus his advice is with this exception excellent and the reviewer agrees most heartily with his statements as to the necessity of search for and removal of focal infections.

The section devoted to treatment of malignant neoplasms is full of sound medical advice and the reviewer with one exception can give it his most hearty approval. This exception is that the reviewer is in favor of the so-called massive x-ray dose in basal cell epithelioma rather than repeated small doses. The advice given about x-rays in psoriasis is excellent. As far as the benefits from gold or manganese in this condition the reviewer has never had any success with either the intravenous injection of gold compounds or the intramuscular injection of a colloidal manganese preparation.

The subject of syphilis is thoroughly covered and the

author's methods can be endorsed.

In spite of the above criticisms the book is well worthy of careful study and will prove especially valuable to the general practitioner and also the experienced dermatologist can find many things which will be of use to him.

BINFORD THRONE.

The Nutrition of Healthy and Sick Infants and Children for Physicians and Students. By E. Nobel, C. Pirquet and R. Wagner. Second Revised Edition. Authorized translation by Benjamin M. Gasul, B.S., M.D. Octavo of 243 pages, illustrated. Philadelphia, F. A. Davis Company, 1929. Cloth, \$3.50.

Of course this book presents the "Pirquet system of nutrition." Having devised a new word to designate his food unit, the "Nem," Dr. Pirquet evidently felt the urge to manufacture a great new vocabulary and so has constructed quite a number of compound words in ingenious fashion.

The whole system is ingenious and harmonious, though somewhat artificial, like a one man cult, and, if one

knew nothing of baby feeding, and where others are employing the same words, doubtless useful.

However, this reviewer's largest interest in the book is in seeing how differently the same ideas may be made to look. In essential particulars the Austrian authors are feeding their babies as we do, but it doesn't look We see no reason for forsaking our mnemonics or forms of expression for these.

The book is a brief presentation, almost a student's manual, of feeding by the Pirquet system W. D. L.

THE TREATMENT OF DIABETES MELLITUS WITH HIGHER CARBOHYBRATE DIETS. A TEXTUDO for Physicians and Patients. By William D. Sansum, M.S., M.D., Percival A. Gray, Ph.D., M.D., and Rutin Bowden, B.S. 16mo of 309 pages. New York and London, Harper & Brothers, 1929. Cloth, \$2.50. (Harper's Medical Management) Monographs.)

The pendulum of practice has swung away from the use of high fat dicts in diabetes and in their own work these authors report good results. Upon a standard diet adjusted to insulin they replace 100 gms, of fat with 130 gms, of carbohydrate and this requires no change in insulin dosage, while the urine remains free from sugar. The additional carbohydrate stimulation actually increases tolerance. This small book should be welcomed by the profession, since it is so clear in its treatment of fundamentals that all types of readers will find it acceptable for their purposes.

THE MOST NEARLY PERFECT FOOD. The Story of Milk. By SAMUEL J. CRUMBINE, M.D., and JAMES A. TOBEY, Dr. P.H. 12mo of 292 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1929. Cloth, \$2.50.

It is a very pleasing sign of the times when milk is thought important enough to have books written about

its properties and its virtues.

The book takes up, in an interesting way, the history of the use of milk in ancient and modern times, and its properties including its vitamine content. There is also a chapter on milk products, butter, cheese, ice cream, buttermilk, fermented milks, and concentrated milks.

Helen Rich Baldwin has a section in which she gives some very practical milk recipes that are of service in the attractive preparation of milk so as to provide variety and thus avoid tiring of the patient's taste for plain milk, itself. As is well known by physicians, a very important property of milk is its containing in a very easily assimi-lated form liberal amounts of calcium and phosphorus.

The authors quote a statement which appeared in the Journal of the American Medical Association commenting on Professor Sherman's notable experiments on cal-cium, namely: "The dietary rule of a quart of milk each day for every child is much more than a precept based on individual opinions or drawn by analogy from the results of feeding experiments with lower animals: it now rests on scientific evidence obtained by extensive and intensive experiments directly upon the children themselves."

It is rather interesting to note in view of recent experiments as to the influence of milk on longevity, that Sweden which has an expectancy of life some six years longer than that of the United States has a milk consumption per capita of seventy gallons a year compared with an average of hity-five gallons in this country.

Milk is easily the most important single food available for the human race, and any publication which will give more information and throw more light on such an important subject should be welcomed, especially by those who are concerned with the care and nutrition of the growing child. WM. HENRY DONNELLY.

# "Upon the Advice of My Physician"

HE majority of men and women who come to McGovern's Gymnasium to correct some physical condition are sent there directly by their physicians.

For more and more physicians are realizing the futility of leaving patients to their own resources when exercises are prescribed, and have learned that through individual attention at McGovern's, their instructions will be faithfully carried out.

A work-out will convince you of the superiority of the McGovern Method. Let us send you a guest card. No obligations, of course.

#### (Continued from page 618)

vision both as to need and as to opportunity. I shall briefly give some comments made by the physicians to the nurses on the Pre-School Summer round-up. "Doctors prefer to turn the work over to the health officers." "Doctors willing to cooperate, but only a few will set a day. One said he would go over them when he found them in the homes. Are 'doubting Thomases' as to results." "County Superintendent sent out letters urging medical examination of children, complete survey made by teachers, doctors willing, but no definite plan offered." "No cooperation by teachers or physicians." "Local doctors thoroughly cooperative, no fee charged." "Work should be done by the health officers." "Too busy to examine. Prefer health officer." And comments, so on, throughout the counties.

"Physicians have not grasped the full benefit to themselves and to the children to be derived from this plan as outlined by the Medical Society of Virginia and the State Department of Health. The doctors must first 'be sold' to this plan and then 'sell' it to the parents; when this is accomplished it will not be long before the parents will fully realize the importance of having children of pre-school age examined every six months

by their family physicians.

"Mecklenburg County has met this by its county society heartily entering into the plans of the State Department of Health and the State Department of Education. The county society accepted the call of the State Department of Health and inoculated 1,800 children of the county at schools with toxin-antitoxin, the county society agreeing to do this work for the same amount that the State Department of Health would receive. This fund was paid to the Mecklenburg County Society and was distributed, each member of the society receiving the same amount, whether he inoculated one hundred, or several hundred children. The county society has entered into the plan of pre-school child examination and agreed upon a uniform fee of \$1.00 for each examination, believing that the family physician and the community will receive equal benefit from this work. At the last meeting of the Mecklenburg County Society, each member present, who graduated more than ten years ago, agreed to take the post-graduate course in Child Welfare Work as outlined by the Medical Society of Virginia, and thus equip himself for this great work of Child Conservation."

#### HEALTH EDUCATION IN GEORGIA

The President of the Medical Association of Georgia, Dr. W. R. Dancy, has written an editorial on Health Education Week, which appears in the April issue of the Journal of the Medical

(Continued on page 621-adv. xv)

(Continued from page 620-adv. xiv)

Association of Georgia. After outlining the purpose of the movement the President says:

"For this purpose an organization was perfected composed of a committee with representatives from the Medical Association of Georgia, State Board of Health of Georgia, Emory University School of Medicine, University of Georgia Medical Department, and the Division of University Extension. With these, other bodies have agreed to co-operate—namely, the Woman's Auxiliary to the Medical Association of Georgia, the Parent-Teacher Association, and the State Tuberculosis Association. Locally, chairmen have been appointed and these will develop their plans of the meeting.

"The Health Education Week is one of the greatest projects which has ever been undertaken by this association. It has the possibilities of being the most far-reaching event that has been proposed for years. It will, I hope, have the happy result of welding into closer union for a common good the several great and influential bodies working on this program. It should awaken more interest in a large number of members of our Association, because men are aroused by an active organization which gives them certain duties to perform in its behalf, and I might say there will be more active workers of the profession in this campaign than have ever before worked for their Association at one time. will also be educational to those who address audiences, as they must necessarily prepare their addresses. But above all it will teach the great lesson of unselfish labor in behalf of the people by the profession and other associated bodies in the Health Education Week campaign, and finally it will transmit valuable information about prevention of disease, which will elicit the co-operation and support of the people as a whole, in the work against disease by organized medicine and health bodies.

"It is proposed to hold health meetings in one hundred cities in Georgia during Health Education Week, May 5th to 10th, and we desire all physicians who wish, to take an active part. Notify your local chairman or the secretary of the State Association."

The editorial is followed by another on the cooperation of Fulton County, in which Atlanta is located. The editorial says:

"This appeal is to the individual member to the end that collectively we may reach a goodly proportion of our population with the Good Health Message' during the first week in May. The 'Annual Round-Up' of our local Parent-Teacher organization has joined with us this year, which guarantees the enthusiastic help of this splendid group. The Woman's Club, the

Fifth District Dental Association, the City and County Health Departments, the City School System, the Auxiliary of the Fulton County Medical Society, the City Government, have all assured us of their hearty cooperation and have offered the facilities of their standing committees on Health Extension Education. Lastly, but of outstanding import, our own society has voted financial aid in a substantial amount to defray certain necessary expenses connected with this campaign. Such a magnanimous spirit cannot fail to impress the people who have thought of us too much in the past in terms of exploiters of their physical frailties. But we need, even more than money, the willingness on the part of each member to respond to calls for personal service which the magnitude of the job will require."

The Journal prints a proclamation by the Governor of Georgia announcing the Health Week:

#### GRADUATE COURSES IN OKLAHOMA

The Journal of the Oklahoma State Medical Association for March contains the following description of graduate courses in the State:

"Very few people realize the tremendous importance of the University of Oklahoma. Extension work is available not only for physicians and the medical profession, but for practically every type of citizen. Under the urge of ethics and the demands of the cause of right and justice, the legal profession has recently been and is now undergoing a very close scrutiny, especially as to irregularities and type of misconduct formerly ignored.

"The medical department of the university has already presented many unusual and more worthwhile courses to physicians in various parts of the State. These have been held principally in Oklahoma City as it is the most logical point by reason of being the head-quarters of the medical school. But courses have been held in Tulsa and Muskogee. A few months ago an editorial in this Journal strongly urged physicians of the State to consider, wherever a sufficient number could be gotten together, such courses as might be desired.

"Speaking from the personal standpoint, the writer received a great deal of help at a minimum cost from a course in anatomy and cadaveric surgery, held in Muskogee, the course covering a term of nine weeks, the cost to each of the fourteen participants, \$60. Certainly no one can acquire this service by going away for many times the amount involved. Instructors for this work are rather limited so physicians should begin a long time in advance to lay their plans in order to accomplish their desires."

#### PREVENTIVE MEDICINE IN MINNESOTA

It is remarkable with what unanumity the officers of the State Medical Societies stress the importance of the practice of preventive medicine by family doctors. Dr. S. H. Boyer, President of the Minnesota State Medical Association, writing on the President's Page of the March issue of Minnesota Medicine says:

"The physician must become health-minded. He must learn to look upon himself as a health physician, i.e., one who is ever on the alert for the recognition of the earliest and hidden signs of disease; one who is ever on the alert to avail himself and his people of the accepted methods for prevention of illness.

"The campaign for wiping out diphtheria will be in full swing before long and it will become the duty of each and every one of us to aid earnestly in putting into effect plans for the general use of toxin anti-toxin.

. "The method by which this preventive treatment may be given to large numbers of children will vary in different localities Whether it shall be done by local doctors, by the health department or by other agency is for the local profession to decide. It would seem that the logical way would be for the local profession to treat those who are not indigent; the rest should be taken care of at public expense.

"It is our duty to live up to our ancient traditions. The public looks to us these days to prevent disease. They are calling to us. We cannot fail them. The physician in every locality in the state should take the initiative in this work. They can commandeer all the organized health agencies to their service. They can, if they so desire, have the help of the exension service of their Committee of Hospitals and Medical Education, their Committee on Public Health Education, and of any individuals or groups they might consider helpful. They have but to ask to receive.

"Physicians! Start this campaign of education and carry it to its logical and beneficent conclusion!"

# Reducing the risk in pregnancy

RIGHT red lips, dry body surface, marked exhaustion and low blood pressure, spell acidosis during labor.

It is easier to prevent it during pregnancy than to treat it during labor. A teaspoonful of Alka-Zane in a glass of water, or half milk and half water, is a safe, certain and reliable preventive of acidosis as a complication of pregnancy. It is easy to take, too.

Final decision on the true worth of Alka-Zane rests with the physician. We will gladly send a twin package, with literature, for trial.

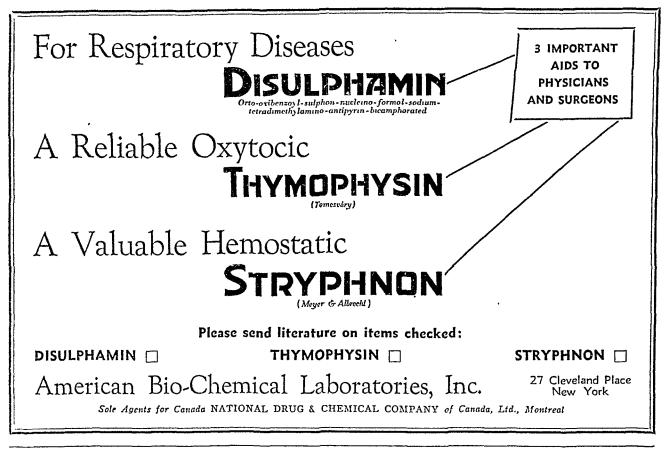

Alka-Zane is a granular, effervescent salt of calcium, magnesium, sodium, and potassium carbonates, citrates and phosphates. Dose, one teaspoonful in a glass of cold water.

Alka-Zane

for Acidosis

WILLIAM R. WARNER & CO., Inc., 113 West 18th Street, New York City

#### ANNUAL MEETING IN TEXAS

The annual meeting of the State Medical Association of Texas will be held on May 6-8, in Mineral Wells. The program is printed in the April issue of the State Journal and among the features are public health lectures described as follows:

"The Committee on Public Health Lectures, headed by Dr. J. H. McCracken of Mineral Wells, has arranged for a series of public health lectures by distinguished members and guests of the Association during the session, to be delivered from the pulpits of the churches in Mineral Wells and adjoining communities, and before such civic clubs as will offer an opportunity during the several days of the meeting. These lectures comprise an important but unofficial part of the annual session."

The Society conducts exhibits of both a scientific and a commercial character. The Scientific Exhibits are described as follows:

"The Scientific Exhibits will be displayed on the ground floor of the Baker Hotel, directly beneath the main lobby and near the Coffee Room, barber shop and other popular sections of the hotel, where they may be viewed at leisure and under most satisfactory conditions.

These exhibits will include many interesting pathological specimens, photographs, x-ray films and statistical tables, all conveniently and interestingly arranged for the busy visitor. There will be actual demonstrations and moving picture demonstrations, full announcement of all of which will be made at the proper time and place."

Among the eighteen exhibits are the fol-

lowing:

X-ray studies of the cecum, by Dr. R. P. O'Bannon, Fort Worth.

Photographs of cancer cases, Dr. J. M. Mar-

tin, Dallas.

Mounted specimens of aneurysms of the arch of the aorta, University of Texas.

Golf is featured in the following description: "The Golf Committee (local) has arranged with the Mineral Wells Country Club for the use of their 18-hole golf course, by all members, visitors and guests, during the entire session.

"The usual tournament will be held, under the rules adopted at El Paso in 1927, by the Texas State Medical Golfers' Association. There will be two trophies for the main competition—the Hotel Paso del Norte cup for

(Continued on page 625-adv. xix)

(Continued from page 624-adv. xvni)

low gross score, and the Orndorff Hotel cup for low net score. There will be several other prizes presented for second and third low gross scores, second and third low net scores, fewest number of putts. lowest score on the five par three holes, etc. Mr W F. Wright of Mineral Wells, is Chairman of the Golf Committee. He will be glad to receive entries and furnish further information concerning rules, conditions, etc."

A curious provision of the By-laws of the State Society is that regarding the scientific

papers, as follows:

"Papers presented by members of the Association must have first been read in full before a component county society, or, where a component county society is not available for this purpose, the district society of which the author is a member. The secretary of such society shall certify to the section secretary that such paper has been so read. It shall be the duty of the officers of sections to ascertan from members who are on their respective programs whether this requirement has been met, and they shall refuse to pemit the reading of such papers before their respective sections unless this By-law has been complied with."

#### ADVERTISING IN COLORADO MEDICINE

Progress in the advertising section of Colorado Medicine, the organ of the State Medical Societies of Colorado and Wyoming, is described in the following statement in the May issue of the journal by Mr. II. T. Sethman, Executive Secre-

tary of the Colorado State Society:

"In February we called attention to a sizeable increase in local advertising and pointed out that the budget promise of a \$750 increase in net advertising receipts for 1930 would be exceeded. Even then it appeared that the estimate of three years for taking Colorado Medicine "out of the red" was too conservative. More remunerative advertising was obtained, and the usual eighteenor twenty-page advertising section was getting crowded.

"With this issue the advertising section increases to twenty-eight pages. More than a score of new advertisers make their bow to the profession. Colorado Medicine is closely approaching the fully self-supporting basis.

"This means progress has been made. It means more, It means Colorado Medicine is rightly recognized as the advertising medium for reaching the medical profession of two states

"Both old and new advertisers are supporting the publication owned by the medical profession. They deserve and will expect reciprocal support. They expect patronage from the profession, or they will seek other advertising mediume"

# NEW JERSEY COMMENT ON THE NEW YORK LAW ENFORCEMENT

The April issue of the Journal of the Medical Society of New Jersey compliments New York State on the enforcement of its Medical Practice Act. After quoting the figures given out by the New York State Board of Medical Examiners the editor comments as follows:

"These figures show excellent results, but they do not tell the whole story by any means. They indicate that once an offender against the Medical Practice Act is held by a magistrate in New York City the chances of his conviction by the Courts of Special Sessions are exceedingly high. consistent vigor with which the Courts of Special Sessions have meted out proper punishment to these offenders has served notice to the public at large and to illegal practitioners in particular that both the State and the courts mean business in this matter, and that going against the law is a dangerous and losing game. It is hoped that as time goes on the magistrates, before whom the preliminary hearings are held, will develop an equally vigorous reaction to medical quackery.

"Apart from results of the criminal prosecution, the best results are indicated in the almost complete disappearance of the illegal display of Licensed chiropodists and the title of 'Dr.' optometrists not entitled to use the title 'Dr.' have been very cooperative in changing their professional signs, and even those quacks and cultists who still persist in taking chances with the law rarely use the title 'Dr.' Since the title 'Dr.' indicates to the uninformed public the holding-out of a qualified practitioner of medicine, its discontinuance by those not so qualified is the greatest single contribution to the effectiveness of the Medical Practice Act in protecting the public from exploitation.

"A few cases have come to light in which illegal practitioners have been operating in partnership or under the protection of unsuccessful licensed practitioners. In such cases the unlicensed men have been prosecuted criminally and the licensed physicians have been referred to the Grievance Committee for disciplinary action. Space does not permit comment on the excellent work of the Grievance Committee in the discipline of licensed physicians and the adjudication of unwarranted claims against ethical practitioners. During the past year this Committee has heard 59 cases in greater New York City alone and its work in protecting both the interests of public health and of the licensed practitioner of medicine cannot be too highly evaluated."

#### THE ITINERANT PRACTITIONER IN WISCONSIN

The State of Wisconsin has a curious law recognizing itinerant practitioners of medicine which is discussed in the following editorial in the April issue of The Wisconsin Medical Journal:

"'Dr. Quack, famous Specialist will be in your city at the Hotel Graft for one day only The Doctor is licensed in Wisconsin. Consultation and examination free'

"Paid notices, similar to the above, appear from time to time, in the columns of some of our state newspapers.

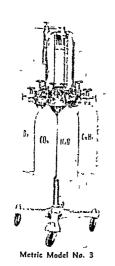

"Is it possible that the members of the medical profession in the towns visited by these miracle men' find themselves inadequately equipped properly to diagnose and treat the cases in their communities?

"Our Wisconsin State Board of Medical Examiners last year issued annual licenses to four titnerants. Regarding one of these outfits the Bureau of Investigation of the American Medical Association has this to say. 'This is the headquarters for a nest of quacks, who go about the midwest states, visiting towns a day or two at a time. The responsibility for the

continued existence of quackery of this sort rests pretty squarely on the local newspapers If some local newspapers refuse to carry their advertisements it is doubtful whether these quacks will attempt to make those particular towns. They are usually careful to see that the renegade physician that they send to a given place is licensed in that state'

"What is an itinerant? Quoting from the Wisconsin Statutes 147 18. 'Itinerant practitioners of medicine, surgery, or osteopathy, or of any form or system of treating the afflicted shall obtain an annual license in addition to the regular license of certificate of registration and shall pay therefor two hundred and fifty dollars per annum. Persons practicing medicine, surgery, or osteopathy, or professing or attempting to treat or heal allments or injuries of the human body, who go from place to place at regular or irregular intervals less frequently than one week, are itinerant practitioners'

"Is the \$250,000 annual fee which they pay a sufficient reason for their continued existence—if not, Why The Itinerant? R.W.B."

## GRADUATE EDUCATION IN TEXAS

The April issue of the Texas State Journal of Medicine contains the following editorial description of graduate courses in Texas:

"Our Summer Clinics will be conducted this year as heretofore, by our two very excellent medical colleges, the University of Texas and Baylor University. It will be remembered that some years ago, at the earnest request of the State Medical Association, the faculties of · these two schools agreed to conduct refresher clinics for practicing physicians. These courses have proven to be very instructive and very They cost the attending physician popular. The purpose of the movement on nothing. our part was to contribute something towards the reeducation of the medical profession. The object of the teachers and of the institutions in which the courses were put on, was to aid and abet such a worthy enterprise.

"Heretofore the courses have followed each other very closely, sometimes overlapping or even running concurrently. This year they will be separated. The course at Galveston will be given in the Spring, and that at Dallas in the Fall. It is thought that perhaps in this way the purposes of the clinics may be met

more certainly."

The editorial closes with the program of a two weeks' course given by the University of .

Texas at Galveston.

## Rheumatic Diseases

Arthritis, Sciatica, Lumbago, Neuritis, and Gout Treated Exclusively

Painstaking diagnosis and therapy as indicated; complete clinical laboratory and department of physiotherapy.

CHANNON LODGE is centrally located and fully ocquipped. Only rheumatic patients accepted. All treatments under the careful and constant supervision of the Resident Medical Director. Reports available to referring physicians, who may at all times retain contact with patients. A completely equipped pathological laboratory supplements diagnoses and treatments. Especially trained staff. Limited accommodations are carefully restricted. Reservations necessary in advance. Inspection cordially invited.

120 acres of woodland privacy; 800 feet elevation with 20-mile view. 42 miles from New York. Tastefully furnished and beautifully landscaped. Accommodations to meet the requirements of patients, single rooms or suites.

hannon Bernardsville, N.Y.

Complete information, rates, trealments, etc., gladly sent upon request to the Medical Director

### JOURNAL OF THE TEXAS STATE SOCIETY

Thirty-two Medical Journals are the organs of the Medical Societies of the several states, and among them the Texas State Journal of Medicine rates high according to a measure which is unintentionally afforded by the New York State Journal of Medicine by its department of "Our Neighbors." This department consists of abstracts and quotations on the special subject of the activities of the other State Societies. The Texas Journal was quoted fourteen times during 1929, a record exceeded only by the Visconsin Journal quoted fifteen times, and equalled only by the Illinois with its fourteen quotations

The April issue of the Texas Journal completes volume 25, and contains an editorial on its make-up during the past year, which will be interesting in comparison with a similar report of the New York State Journal contained on page 508 of the May first issue. A statistical report of volumes 24 and 25 of the Texas Journal is shown in the following

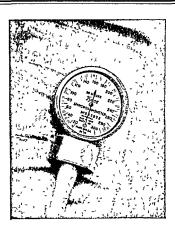

table.

Pages	Volume 24	Volume 25
Scientific Articles	467	413
Editorials	112	97
General News	13	16
Society News	93	84
Women's Auxiliary	20	42
Deaths	24	31
Book Notes	18	25
Transactions	65	56
Miscellaneous	92	108
Advertising	690	726
	<del></del>	
	1594	1598

The editorial comments on the Journal are

as follows:

"An effort was made to reduce the number of editorial pages this year, taking care that sufficient discussion was given to problems which deserved editorial consideration. decrease in the number of original articles was caused by the fact that the papers of the Texas Railway Surgeons' Association were not received until too late for publication in this volume. An effort will be made to publish some of these papers in the May number. which is the first number of Volume XXVI. It also happened that county society secretaries were a little less active in furnishing transactions of county societies. A noted increase is in the Auxiliary department, occasioned by the publication of the Transactions of the Auxiliary for the first time, in the June, 1929, number. However, taken as a whole, the various departments are well balanced, and the present volume is an exceedingly attractive one.'

### Tycos Pocket Type Sphygmomanometer

TWENTY-TWO years ago the first Tycor Sphygmomanometer was placed on the market Although modifications have been made whenever desirable, fundamentally the instrument remains the same today.

Every Tycos Sphygmomanometer has adhered to an indisputable principle-that only a diaphragmtype instrument is competent for the determination of blood pressure. To faithfully record the correct systolic pressure, an indicator's accuracy must not be affected by the speed at which the armlet pressure is released, only a diaphragm instrument can guarantee this. To honestly give the true diastolic pressure, a sphygmomanometer must respond precisely to the actual movements of the arterial wall, again, only a diaphragm instrument can do this. Portable, the entire appartus in its handsome leather case is carried in coat pocket. Durable its reliability in constant use has been proved by many thousands of instruments during the past twenty-two years. Accurate, its precision is assured by relation of the hand to the oval zero. Further information relative to the Tycos Pocket Type' Sphygmomanometer will be furnished upon request.

Write for new 1930 edition of Tycos Bulletin No 6 "Blood Pressure-Selected Abstracts," A great aid to the doctor who wishes to keep abreast of blood pressure diagnosis and technique.

# UNEMPLOYMENT FROM A MEDICAL VIEWPOINT

The May issue of the Journal of the Michigan State Medical Society discusses unemployment as follows:

"It is estimated that there are over four million unemployed workers in the United States at the present time. The actual number may be a great deal larger. The more highly developed society becomes, the more complicated and difficult of adjustment is its economics. It is painfully evident, however, that we in the United States have been living on the fat of the land with little regard for the future. This is seen in the wasteful exploitation of our natural resources. Our standard of living has included not only the so-called necessities of life, but we have come to look upon erstwhile luxuries as necessities. We have placed ourselves under financial obligations that mortgage our future earning power. When the time comes that the demand for certain articles such as automobiles, radios, iceless refrigerators and what not is satisfied and the saturation point has reached, workers are laid off and the unemployment situation is felt not only by the immediate unfortunates, but by the merchants and others.

"It goes without saying the medical profession feel the financial stress early.

"Such subjects as unemployment, industrial statesmanship, directly concern us as members of the medical profession. We have a large share of the burden of the care of the indigent sick. The matter of preventive medicine which affects the whole nation is our concern, and beside it all, we are citizens."

"Industrial statesmanship would have anticipated the possibility of unemployment when times were good and would have undertaken to study the possible situation and its remedy."

#### THE BACTERIOLOGY OF IN-FANT DIET MATERIALS

It is not generally realized, the extent to which Mead Johnson & Company carry their research.

Efficient and systematic as are the research activities carried on for years in their own laboratories, this progressive house is constantly adding fellowships at leading universi-

One of these has recently corroborated\* a fact of great importance to all who feed infants: No Mead Product contains hemolytic streptococci or other pathogenic bacteria.

The significance to pediatricians of this brief statement lies in the fact that the presence of hemolytic streptococcus has been suspected in infant diet products, its relationship to scarlet fever, septic sore throat, enteritis, etc. naturally being a source of alarm.

It is reassuring to all physicians to know that not only have Mead Products never been under suspicion but that from authoritative unbiased sources comes additional proof that as a result of careful technic and long experience, Mead Products are bacteriologically clean and safe to pre-scribe: Dextri-Maltose, Recolac, Casec, Lactic Acid Milk, Powdered Protein Milk.

\* New York State Agricultural Experiment Station Bulletins Nos. 153 and 154. See page xiii.—Adv.

#### SUPPORTING CORSETS AND BELTS

Barnum - Van Orden Supporting Corsets and Belts for thirty years have given relief to thousands of women with relaxed conditions.

Barnum-Van Orden Supports designed to care for each individual case to meet the particular type of support required.

General Ptosis—Movable Kidney— Hernia—General Back Support—Sac-ro-iliac Strain—Maternity Supports and Breast Supports, each type carefully fitted and satisfaction guaranteed to justify the physicians confidence in sending his patient.

Barnum-Van Orden new Combine is a combination of Brassier and Belt without lacings in the back which gives the Princess Silhouette and Abdominal and Back Support and is pleasing to the stylish women, see page xxv.-Adv.

#### A NEW KIND OF SERVICE FOR **PHYSICIANS**

The saving of the mineral salt and vitamin content of food is recognized by competent authorities today as a definite aid in preventive treatment. But, frequently it is difficult for the physician to get his patient to carry out the prescribed dietary program because of the unpalatability of certain most desirable foods through improper preparation.

To aid in overcoming this, a new kind of service for physicians has been established by the Institute of Applied Cookery at 409 Amsterdam Avenue (between West 79th and 80th Streets), New York City. A competent staff of experts is prepared to show the patient or householder how to preserve the natural flavor of the food and to minimize the loss of important food con-This Institute is concerned with no dietary program of its own but is equipped with facilities which are scientific and yet practical for home use. See page xxiv.—Adv.

#### A CALCIUM PREPARATION THAT CHILDREN LOVE

There are two drawbacks to most calcium preparations for oral use—the taste is horrible and assimilation is uncertain. In Olajen, a preparation containing salts of calcium, sodium, potassium, iron and lecithin, the first of these objections has really been overcome. Olajen actually tastes like a creamy fudge. It is claimed for this preparation on the basis of clinical records that absorption is exceptionally good because of its colloidal nature. For samples and literature write Olajen, Inc., 451 West 30th Street, New York City. See page xv.—Adv.

# In New and Modern Hospitals

IN the newest, most modern hospitals throughout the country, the Wappler Monex has come to be regarded as standard X-Ray equipment. In practically every instance it has been selected after careful and searching investigation.

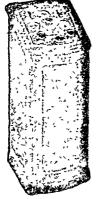

These institutions demand the most efficient and dependable in X-Ray apparatus. Their final choice of the Monex affords conclusive evidence of its superiority.

The advantages that most strongly impress those who carefully investigate the Monex are its ample power, its speed and its silent operation. Radiographs of all body parts are taken with surprising speed, even with heavy patients.
The absence of noise, sparks and fumes, is an important advantage to both patient and operator.

The Monex is immune to atmospheric conditions and can be depended upon to duplicate results accurately. For fluoroscopic examination, exposures of any desired duration are feasible. The Monex is also extensively used for superficial skin therapy.

Bulletin 107-G will bring you complete information regarding the Monex. Mail the coupon for it now.

Old Age often requires a TONIC-

Most physicians have aged patients who, without manifesting any physiological disorder, require a tonic.... Dewey's Dew-Tone and Port fills such a need.... It is a

combination of properly matured Port made from grapes' known to produce wine of a high iron content, glycerophosphates and peptone.... It will aid in restoring them to normal health and a feeling of well being.... Dew-Tone and Port will also be found valuable in post-operative cases and for those who suffer from the wasting diseases .... Dewey's Dew-Tone and Port has no sales distribution and cannot be purchased in any store.... It is only sold direct to physicians and their patients.... We shall be glad to send you a complimentary sample upon request.

I highly recommend dress increasing and the anti-philodelphia with the anti-philodelphia with the anti-philodelphia with the action, has everything in adversed cases, the nearthing of the necessite them and core without pain and danger to the patient."

—From "Pic Relikoerperbehundling des Plabetes." by Professor Dr. Gustan Singer, head physician at the Rudolfstilling. Hospital, Vienna.

# Furuncular and Phlegmonous Complications of Diabetes

IN seemingly hopeless cases, if the general condition, metabolism and local processes do not endanger life, simple and conservative treatment should be partiently applied with the help of careful and persistent esort to minor surgery.

Surgeons, more and more, are inclined towards the Conservative Treatment of Furuncles and Carbuncles, especially those of Diabetics, and some of them even go so far, in many cases, as to refrain from incisions and to rely on outward applications.

# Antiphlogistine

by hastening the disintegration of the exudates and toxins and by stimulating cellular activity, is an appropriate topical application, producing definite physiological reactions, which are the basis of all healing.

## A Dependable Agent For Supplying Calcium In Diffusible Form

KALAK WATER presents a saturated solution of calcium as the bicarbonate.

"Of the inorganic salts of calcium, the bicarbonate was the most effective in raising the blood calcium." (W. H. Jansen—Deut. Arch. f. klin Med. Oct. 1924.)

It is not possible to present calcium bicarbonate as a dry powder or as an effervescent mixture to be added to water. This salt can be maintained as the bicarbonate only in an aqueous solution that is charged with carbon dioxide.

KALAK WATER CO. 6 Church St. " New York City

#### DIET QUESTIONS have GELATINE ANSWERS

# CAN THE BOTTLE BABY HAVE LESS STOMACH DISTURBANCE AND MORE BODY NOURISHMENT?

The answer to these two questions will be found in the same package.

It has been proved by medical research that the addition of 1% of Knox Sparkling Gelatine to the bottle baby's milk modifies the tendency of cow's milk to curdle in the natural acids and enzyme rennin of the infant stomach.

Not only does the gelatine lessen stomach disturbance but, in many cases, increases the absorption of the milk —enhancing the nourishment the infant obtains from its food.

Care should be taken, however, to use only real gelatine—the clear, unsweetened, unflavored, unbleached kind. For more than 40 years Knox Sparkling Gelatine has been regarded by the medical profession as meeting each of these requirements.

Be sure you specify Knox Gelatine—the real gelatine—when you prescribe gelatine for baby's milk.

The following is the formula prescribed by authorities in infant feeding: Soak, for about 10 minutes, one level tablespoonful of Knox Sparkling Gelatine in one-half cup of milk taken from the baby's formula; cover while soaking; then place the cup in boiling water, stirring until gelatine is fully dissolved; add this dissolved gelatine to the quart of cold milk or regular formula.

We have listed here some hooklets which we believe will help you in your practice. Kindly mail the coupon today.

### A Dependable Agent For Supplying Calcium In Diffusible Form

KALAK WATER presents a saturated solution of calcium as the bicarbonate.

"Of the inorganic salts of calcium, the bicarbonate was the most effective in raising the blood calcium."
(W. H. Jansen—Deut, Arch. f. klin Med. Oct. 1924.)

It is not possible to present calcium bicarbonate as a dry powder or as an effervescent mixture to be added to water. This salt can be maintained as the bicarbonate only in an aqueous solution that is charged with carbon dioxide.

KALAK WATER CO.

Patient Types . . .

The Hospital Case

JONFINED to the bed, weak and nervous, the hospital patient under your care is hardly a fit subject for the old-fashioned dras-

tic purge.

Petrolagar has many advantages in maintaining bowel function. It is palatable. It mixes easily with bowel content, supplying unabsorbable moisture with less tendency to leakage. It does not interfere with digestion and is prescribed in preference to plain mineral oil.

Petrolagar restores normal peristalsis without causing irritation, producing a soft-formed consistency that provides real comfort to

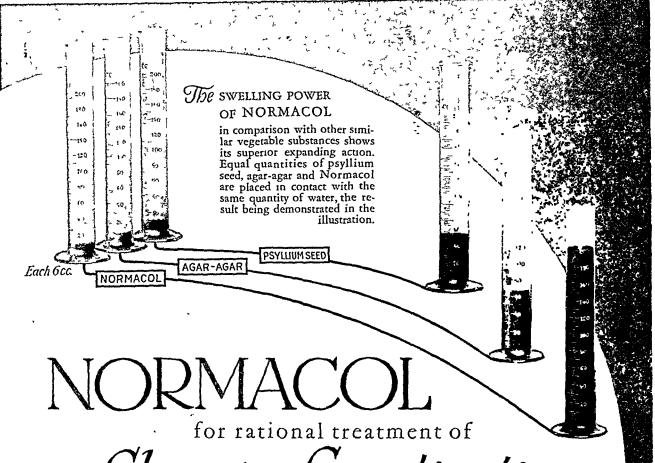

howel movement.

Petrolagar is composed of 65% (by volume) mineral oil with the indigestible emulsifying agent agar-agar.

## Petrolagar

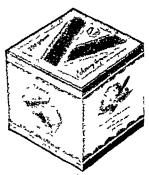

etrolagar Laboratories, Inc.

# Chronic Constipation

is a harmless therapeutic agent which possesses extraordinary swelling properties.

NORMACOL

consists of the coated granules of a species of bassonin sap with about 1% cascara sagrada.

(One-fifth U. S.P. dose to one teaspoonful)

It increases the volume of the residual matter in the bowels, thus establishing a soft and non-irritating bulky evacuation, without pain, griping or digestive disturbances.

DOSE: One to two teaspoonfuls, after meals, taken dry on the tongue and followed by a draught of water, without chewing

Supplied in 100 and 200 gram packages.

Sample and literature upon requests

# SCHERING CORPORATION

110 William Street NEW YORK, N. Y.

#### When Your Diagnosis of Malignancy Has Been Confirmed We Can Help You

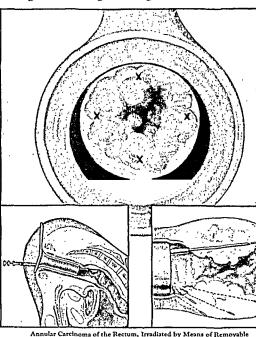

UIETLY, but effectively, The Radium Emanation Corporation has been administering the radium needs of America's most prominent physicians since 1922.

We offer you the same technical counsel, the same extraordinary radium laboratory facilities that have made it possible for surgeons, gynecologists and urologists throughout the United

States and Canada to reinforce their own efforts in behalf of the patient afflicted with cancer.

Very definite changes have taken place in the art of radium therapy. The "hazard and hope" methods of earlier days have been abandoned in favor of a new, more scientific technique, which has completely changed the attitude of the entire medical fraternity towards the surgical use of radium, and radium therapy is rapidly becoming an indispensable element in the armamentarium of every surgeon, gynecologist and urologist.

The Radium Emanation Corporation has contributed in large measure to this modern trend in radium therapy. It gave the medical profession the Removable Platinum-Radon Seed which has made possible so many of the unparalleled results reported recently in the medical press. Through its radium therapy consultants, The Radium Emanation Corporation sponsors the most advanced methods in radium therapy and makes radium available to the individual physician according to the requirements of his particular case.

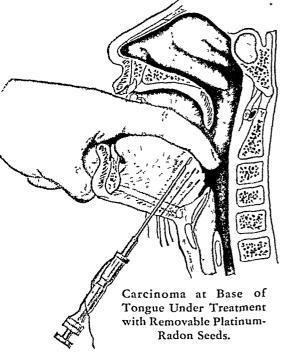

of the Rectum, Irradiated by Means of Removable Platinum-Radon Seeds, Without Radical Surgery.

We have only one ideal-to help you obtain better. results in the treatment of your malignant cases.

If you have malignant cases, for which you are considering treatment, investigate this unique service. Let our radium therapy consultants collaborate with you in the solution of your problems. They will gladly give you the benefit of their own broad experience and you may have their opinion and recommendations without incurring the slightest obligation.

> Send us a history of the case and you will receive immediately a carefully considered plan covering the application of radium.

The type of service we are giving the medical profession will amaze you, unless you are one of the hundreds of physicians whose radium needs we are already administering.

# Now Every Hospital Can Have Radium

Without Capital Investment or Administrative Expense

made adequate provision for supplying the regular or emergency radium needs of hospitals, both large and small, wherever located, at moderate cost. All departmental requirements are quickly and efficiently met and the radium is prepared according to the requirements of each individual case. Instruments and other surgical equipment necessary to properly apply the radium are always provided. If it is desired our radium therapy consultants will collaborate with department chiefs until such time as radium therapy becomes well established as a part of your equipment.

Such a service insures the immediate availability of adequate quantities of radium for every need, without the investment of capital or expense of administration.

We invite correspondence with hospital executives concerning this unique service.

#### We Prepare Radon for Use at Distant Points Without Loss to the Customer

Physicians familiar with the physical characteristics of radon sometimes ask us how we effect deliveries to distant points without loss to the customer. Every applicator which leaves our laboratory has been prepared so that it will contain the precise amount of radon required at the time of use, even though delivery must be effected at a point three thousand miles from New York City. Physicians and hospitals along the Pacific Coast use our service regularly and enjoy the same economies as those located at intermediate points.

#### Special Service Features

With a large active staff in addition to the medical personnel, we offer the medical profession the facilities of the following divisions of our organization:

Post Graduate Courses in Radium Therapy.

Radium Emanation Equipment—Design, Erection and Maintenance.

Library Research. Abstracting. Editing of material for text-books or special papers on medical subjects.

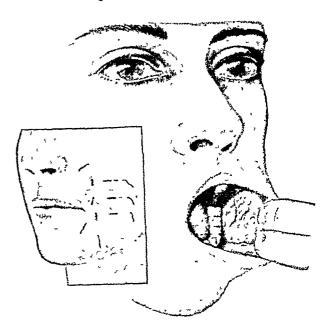

Research. We are prepared to undertake any problem requiring the services of consulting physicists or chemists.

Translations. All languages.

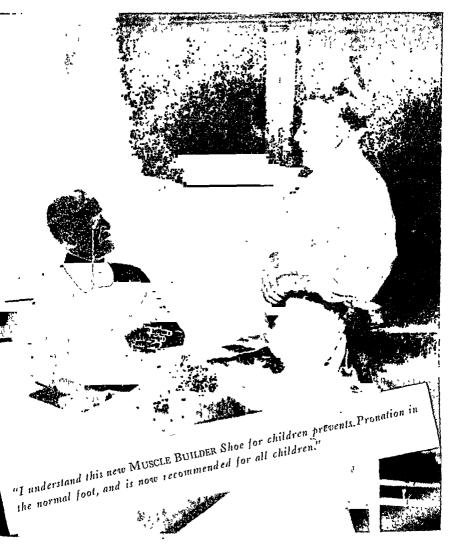

Medical Illustrators. Our medical artists are available for the preparation of anatomical drawings, in full color or in black and white.

Ask for a copy of THERADON, the Monthly Bulletin of our Medical Department, a publication devoted exclusively to methods and technique in the art of radium therapy.
